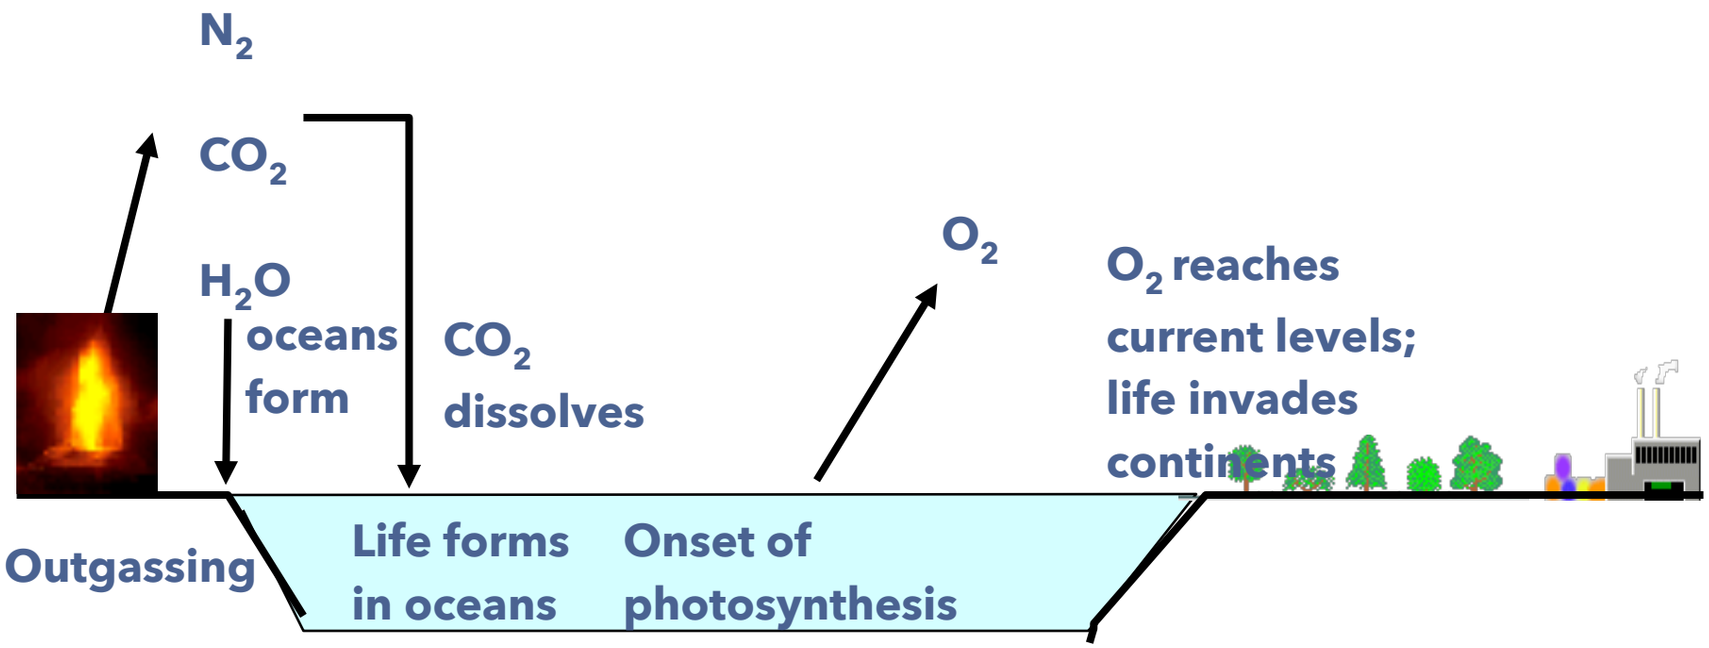
Introduction to the Biosphere-Atmosphere system

Lecture Autumn 2024

Part IV

Steffen M. Noe

How can we model this?



4.5 billion yrs. B.P

4 billion yrs. B.P.

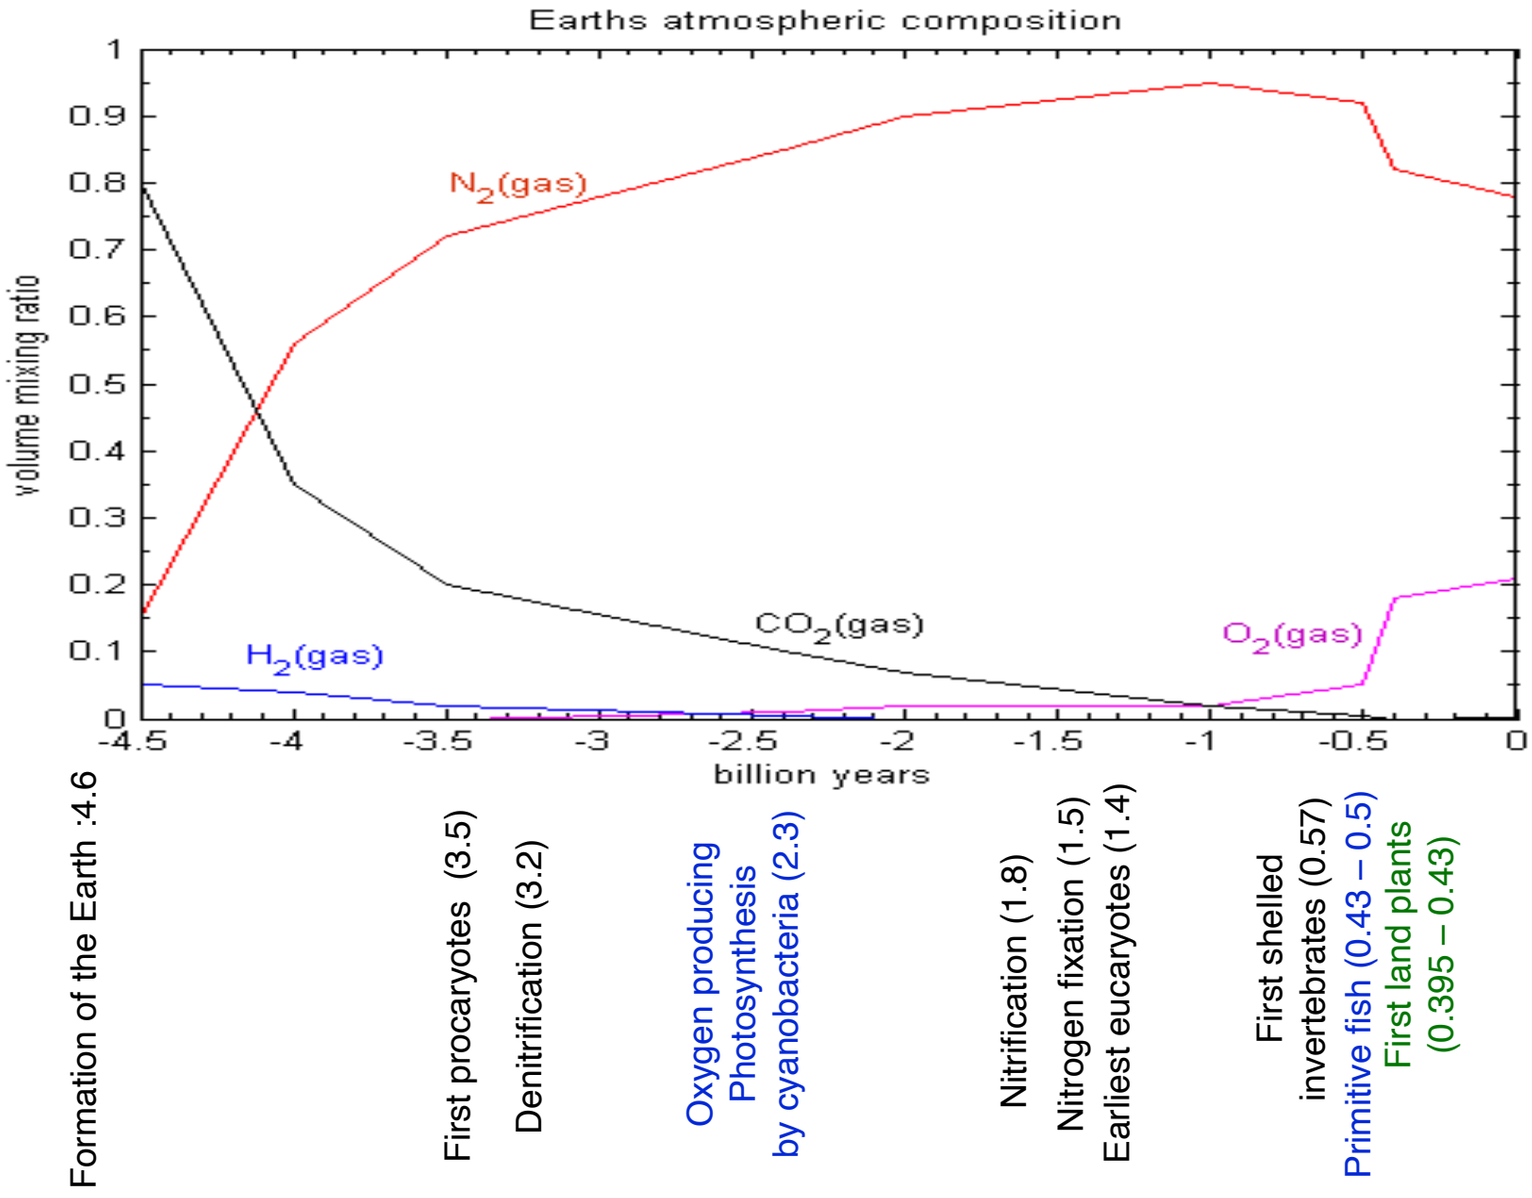
3.5 billion yrs. B.P.

0.4 billion yrs. B.P.

present

D.J. Jacob

History of Earths atmospheric composition

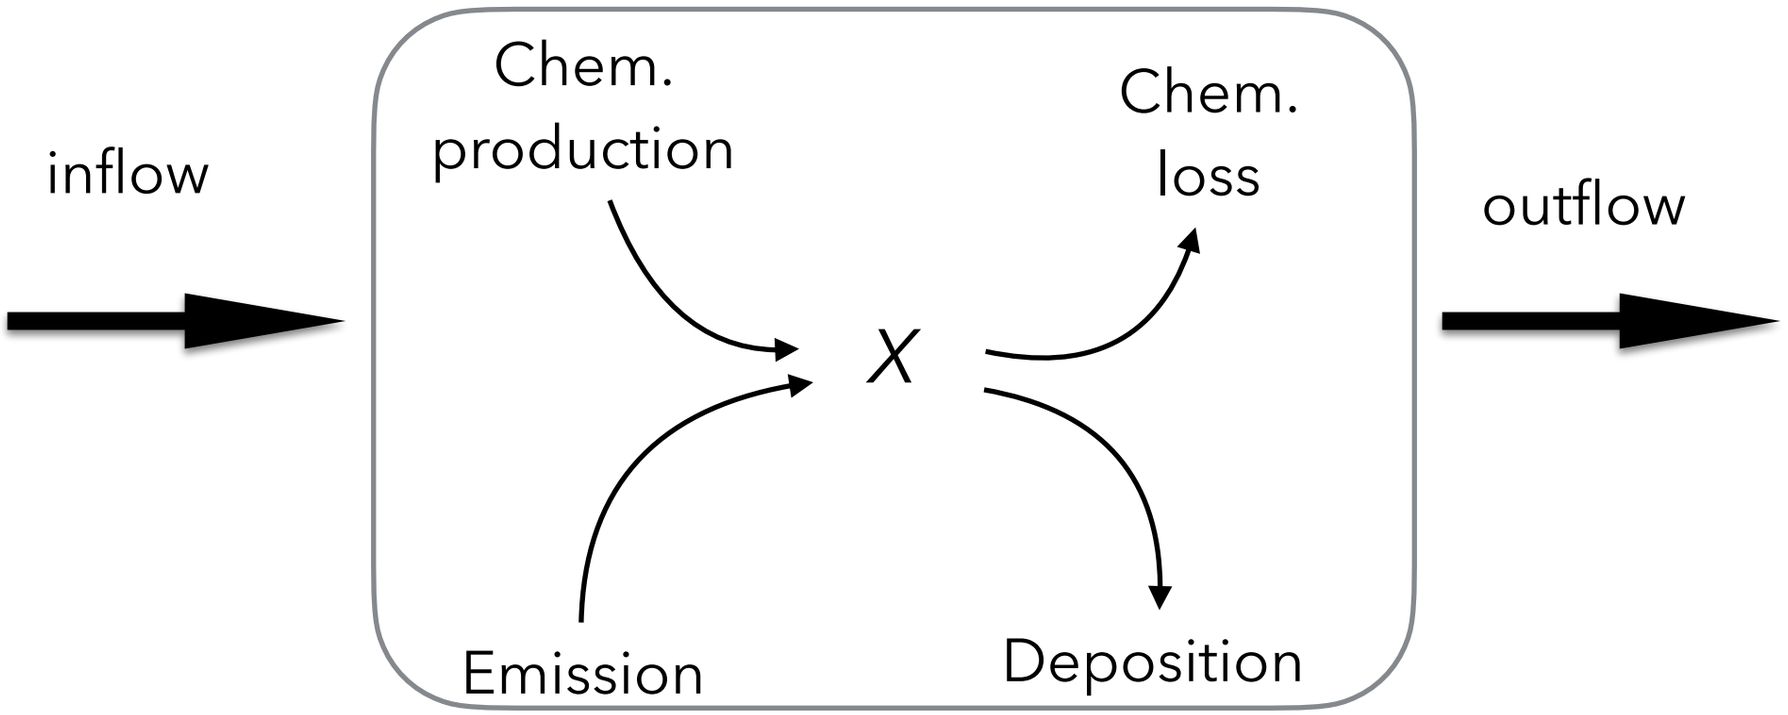


Jacobson, 2002

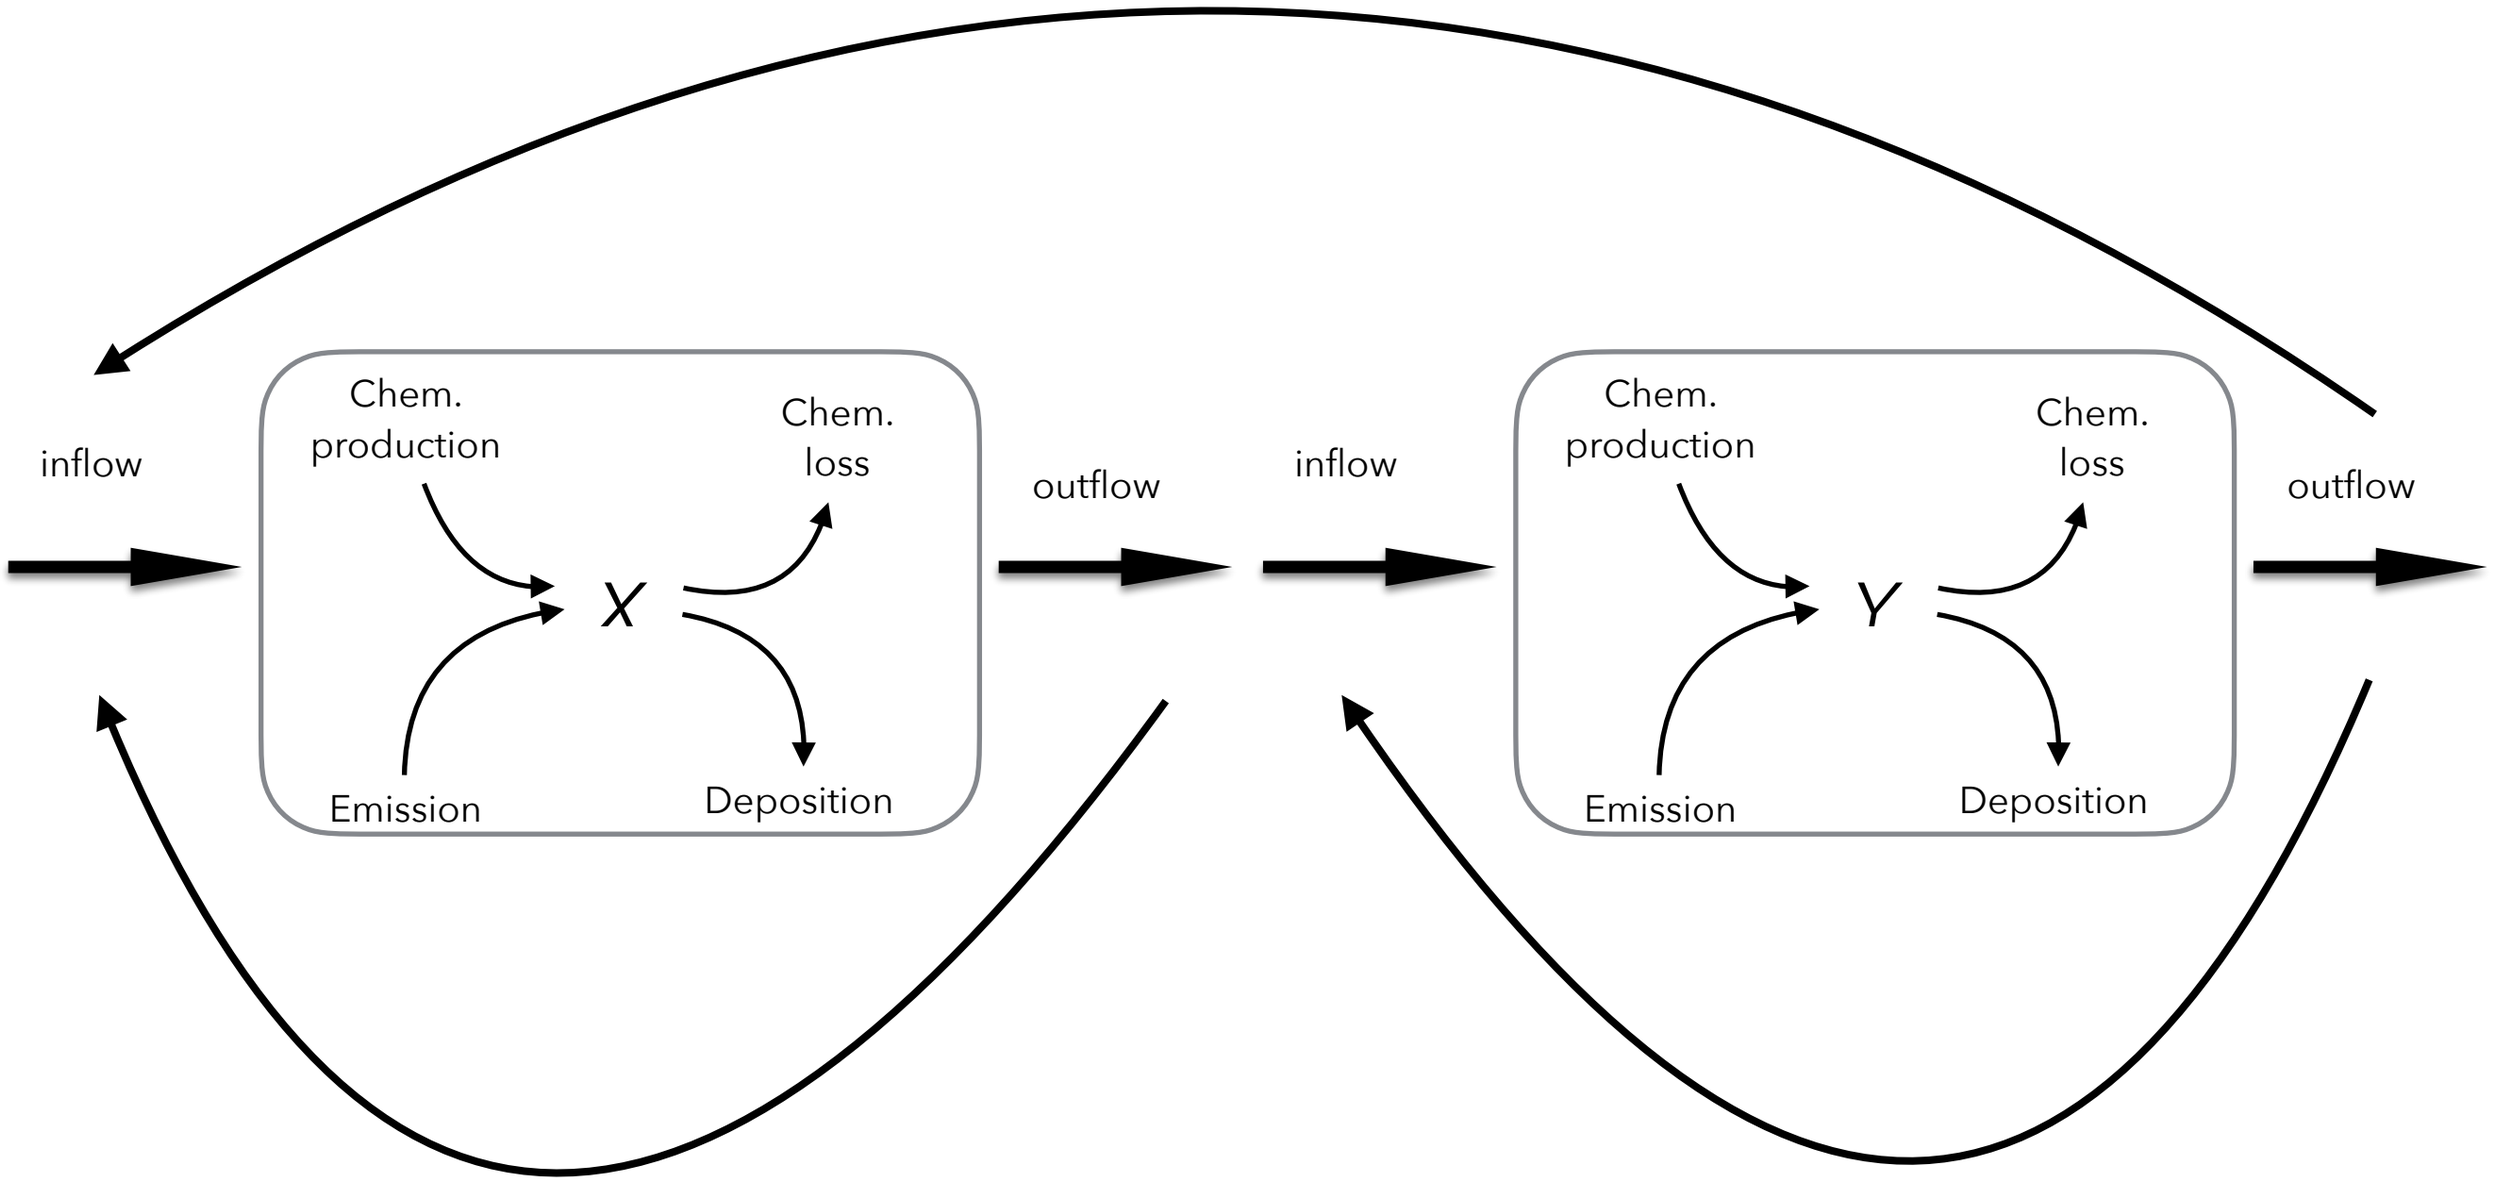
How to describe the Earth system?

- The standard approach is to use **box models**!
- Individual reservoirs are seen as individual boxes!
- Each box has it’s own certain mass (or **inventory**) of elements of interest!
- The migration of those elements is described by **flows** between the boxes!

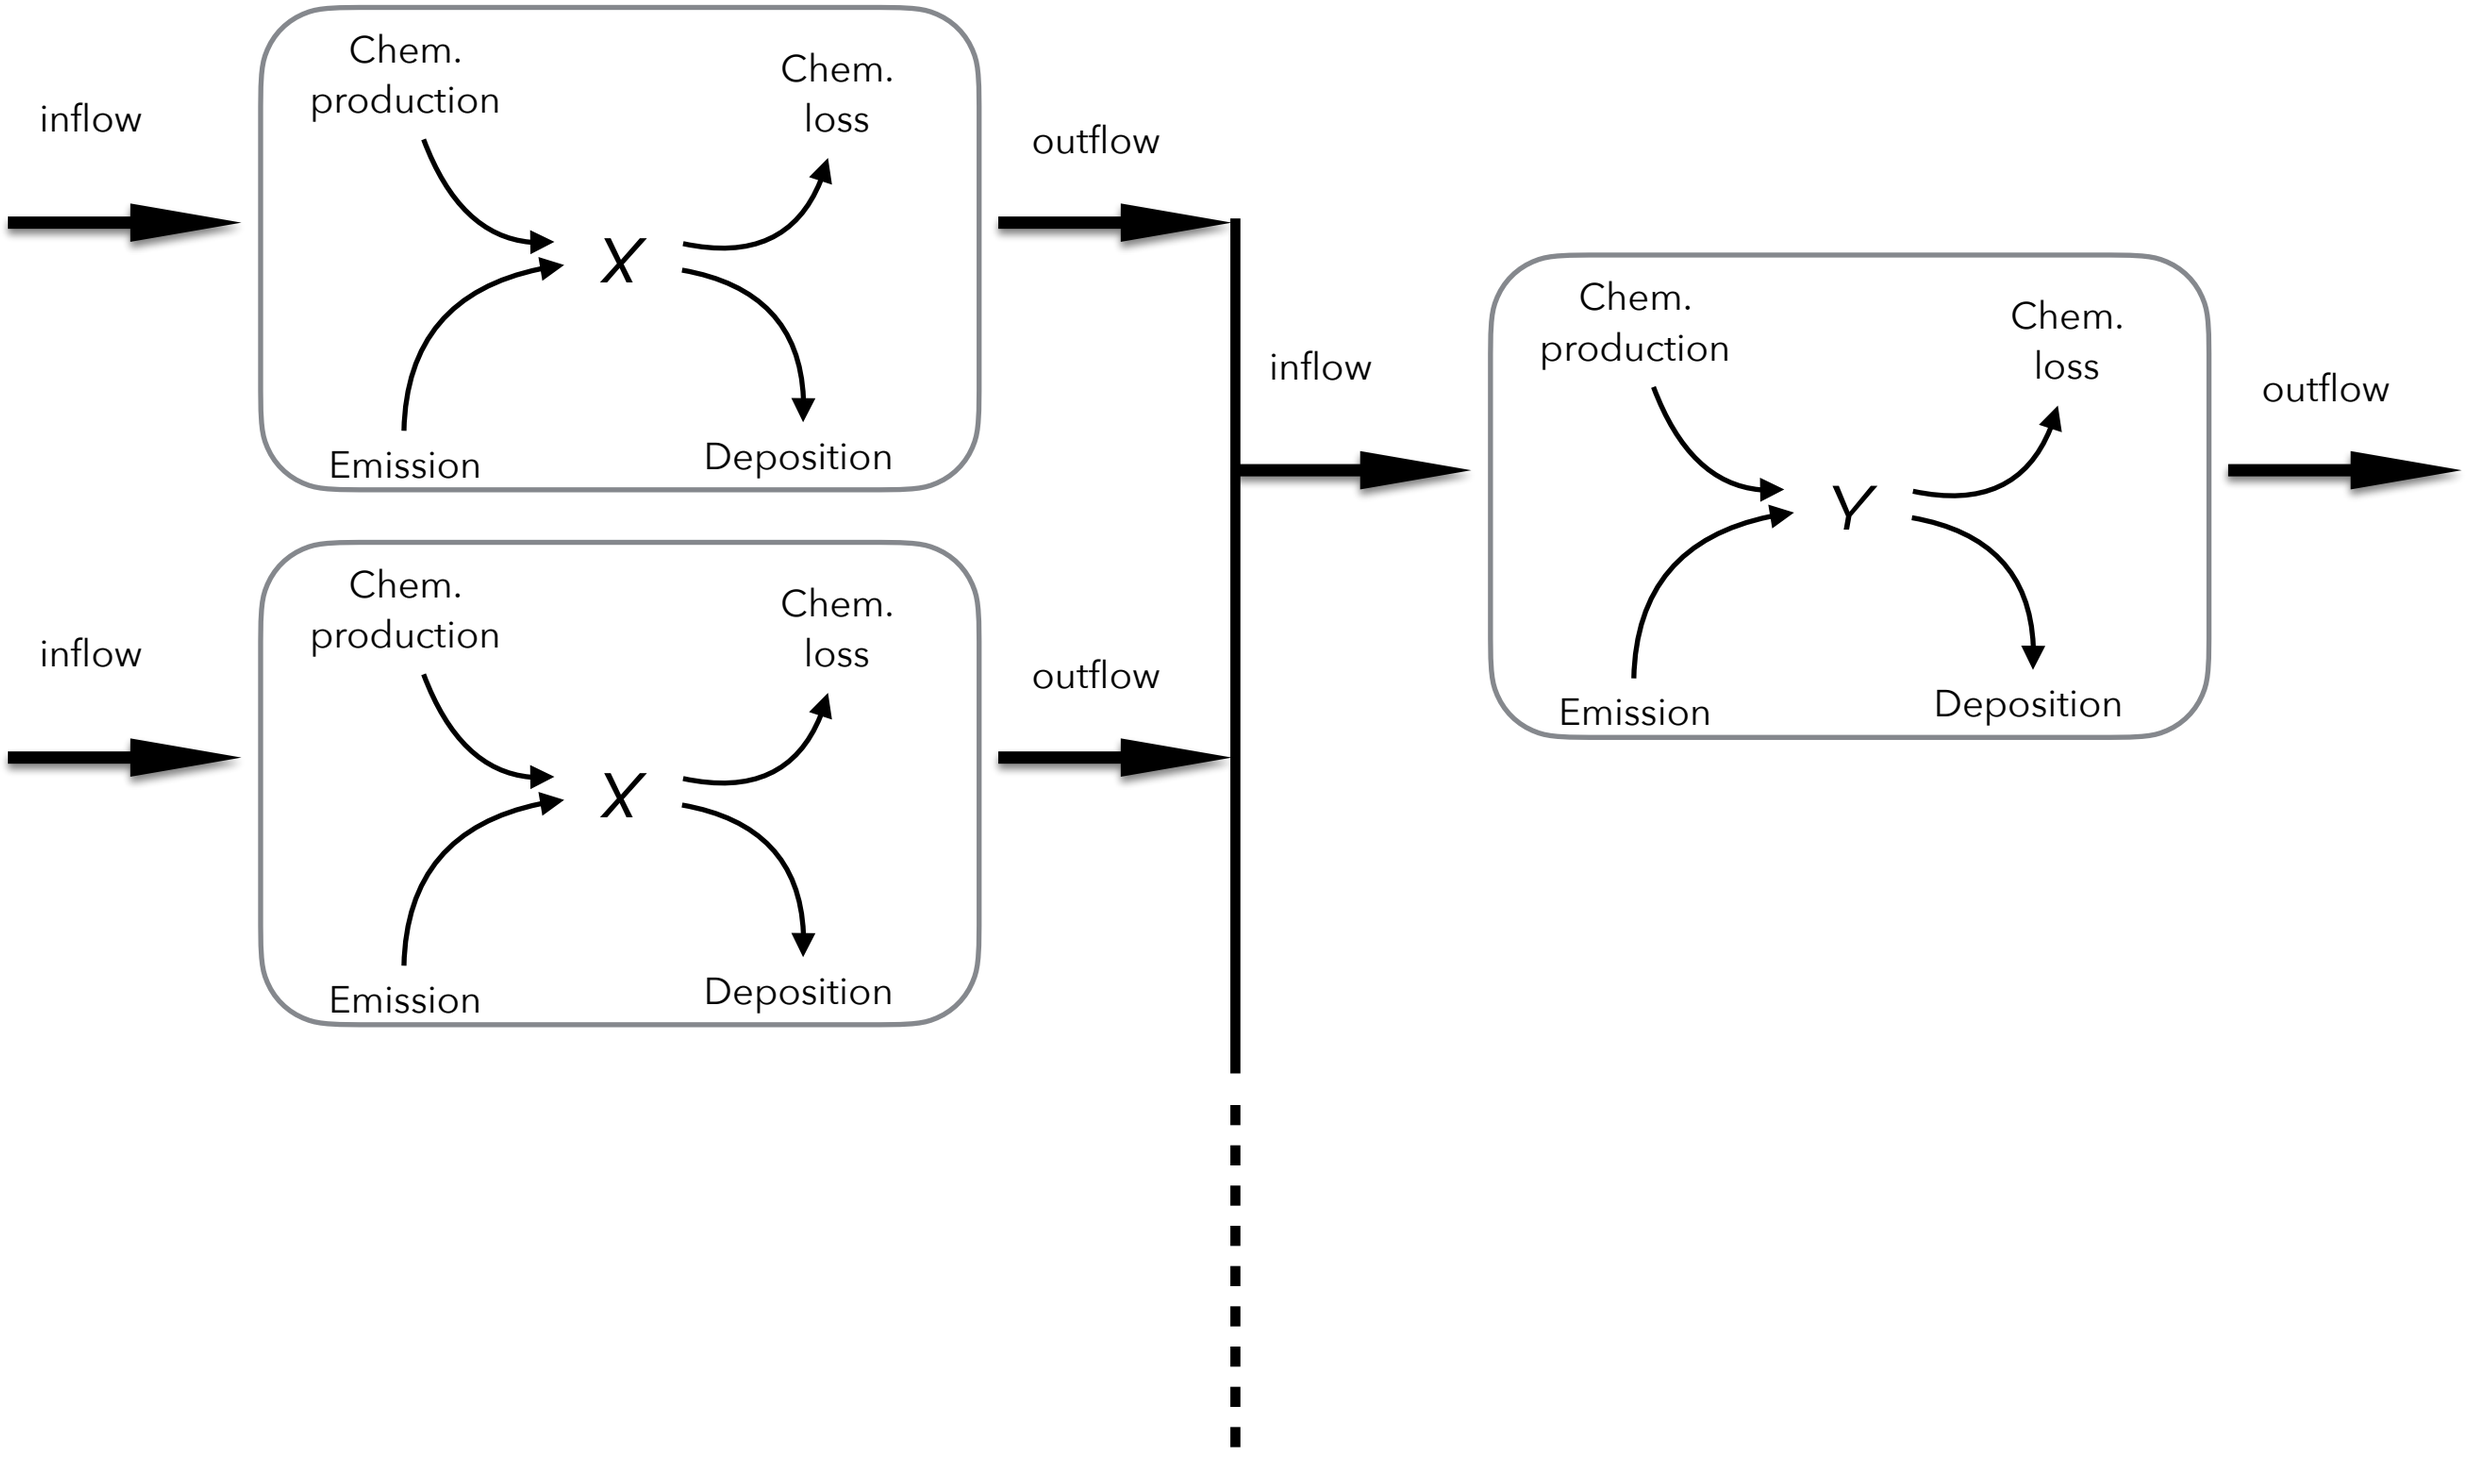
One box model: the building block



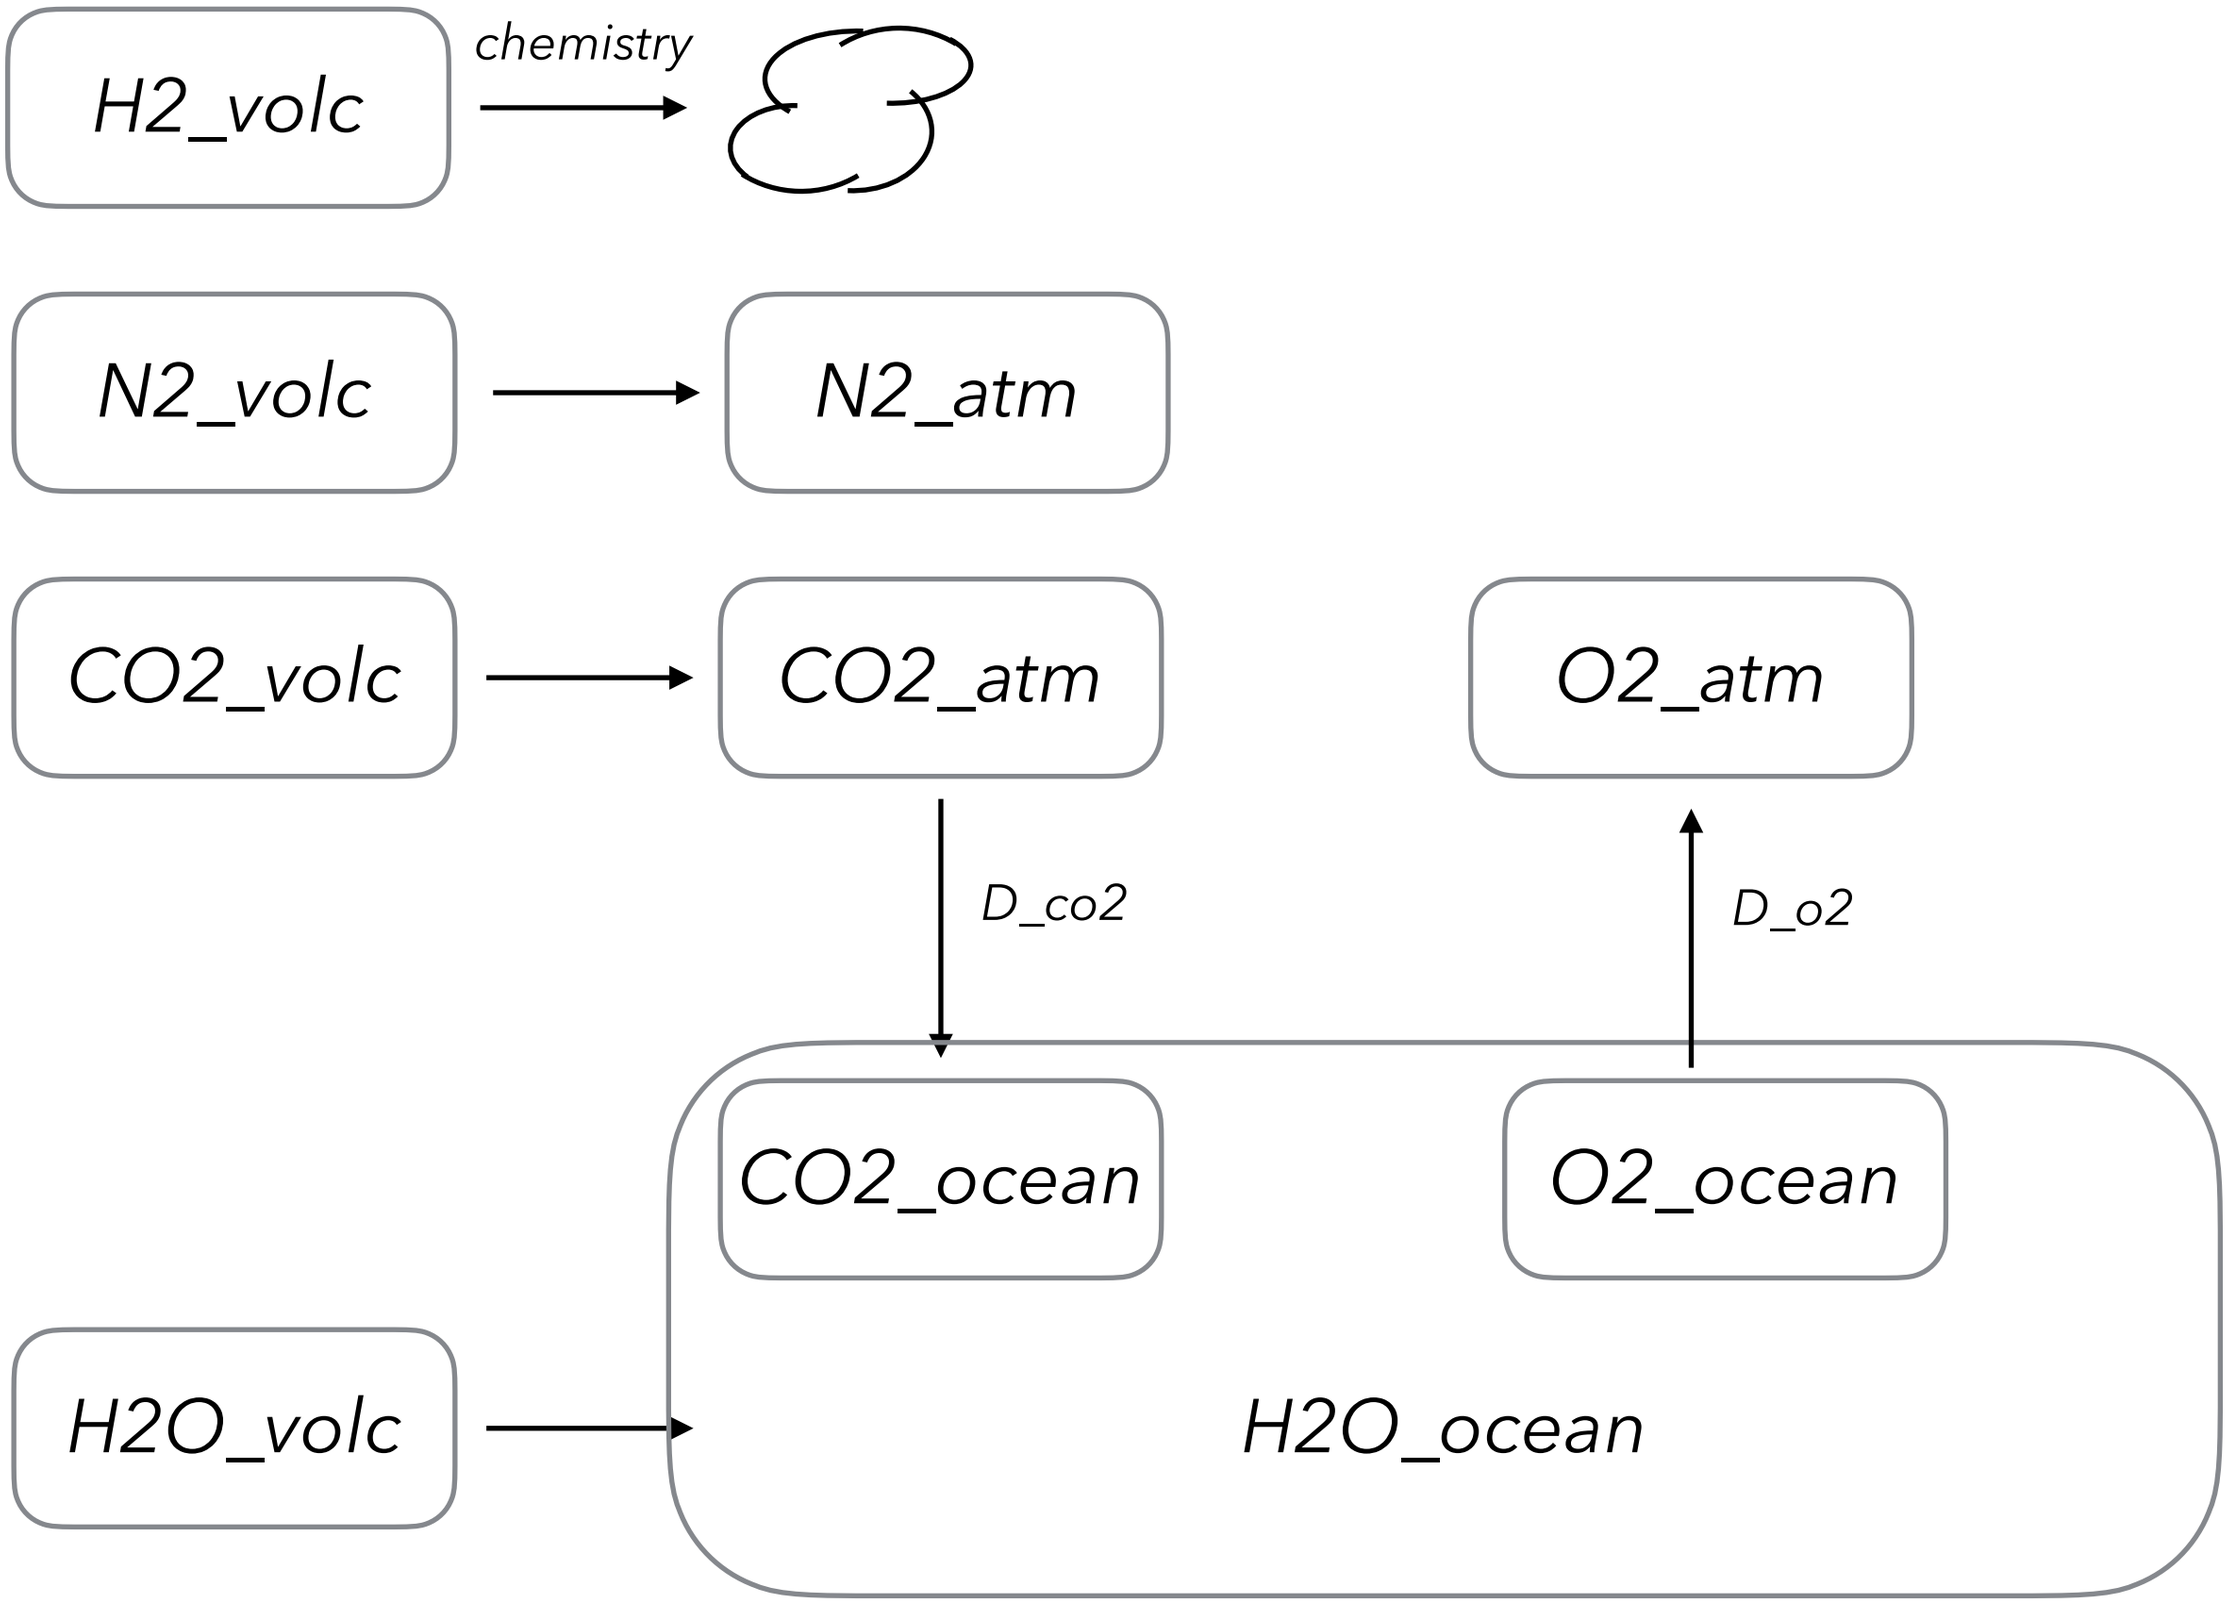
Two box model: we can add feedback



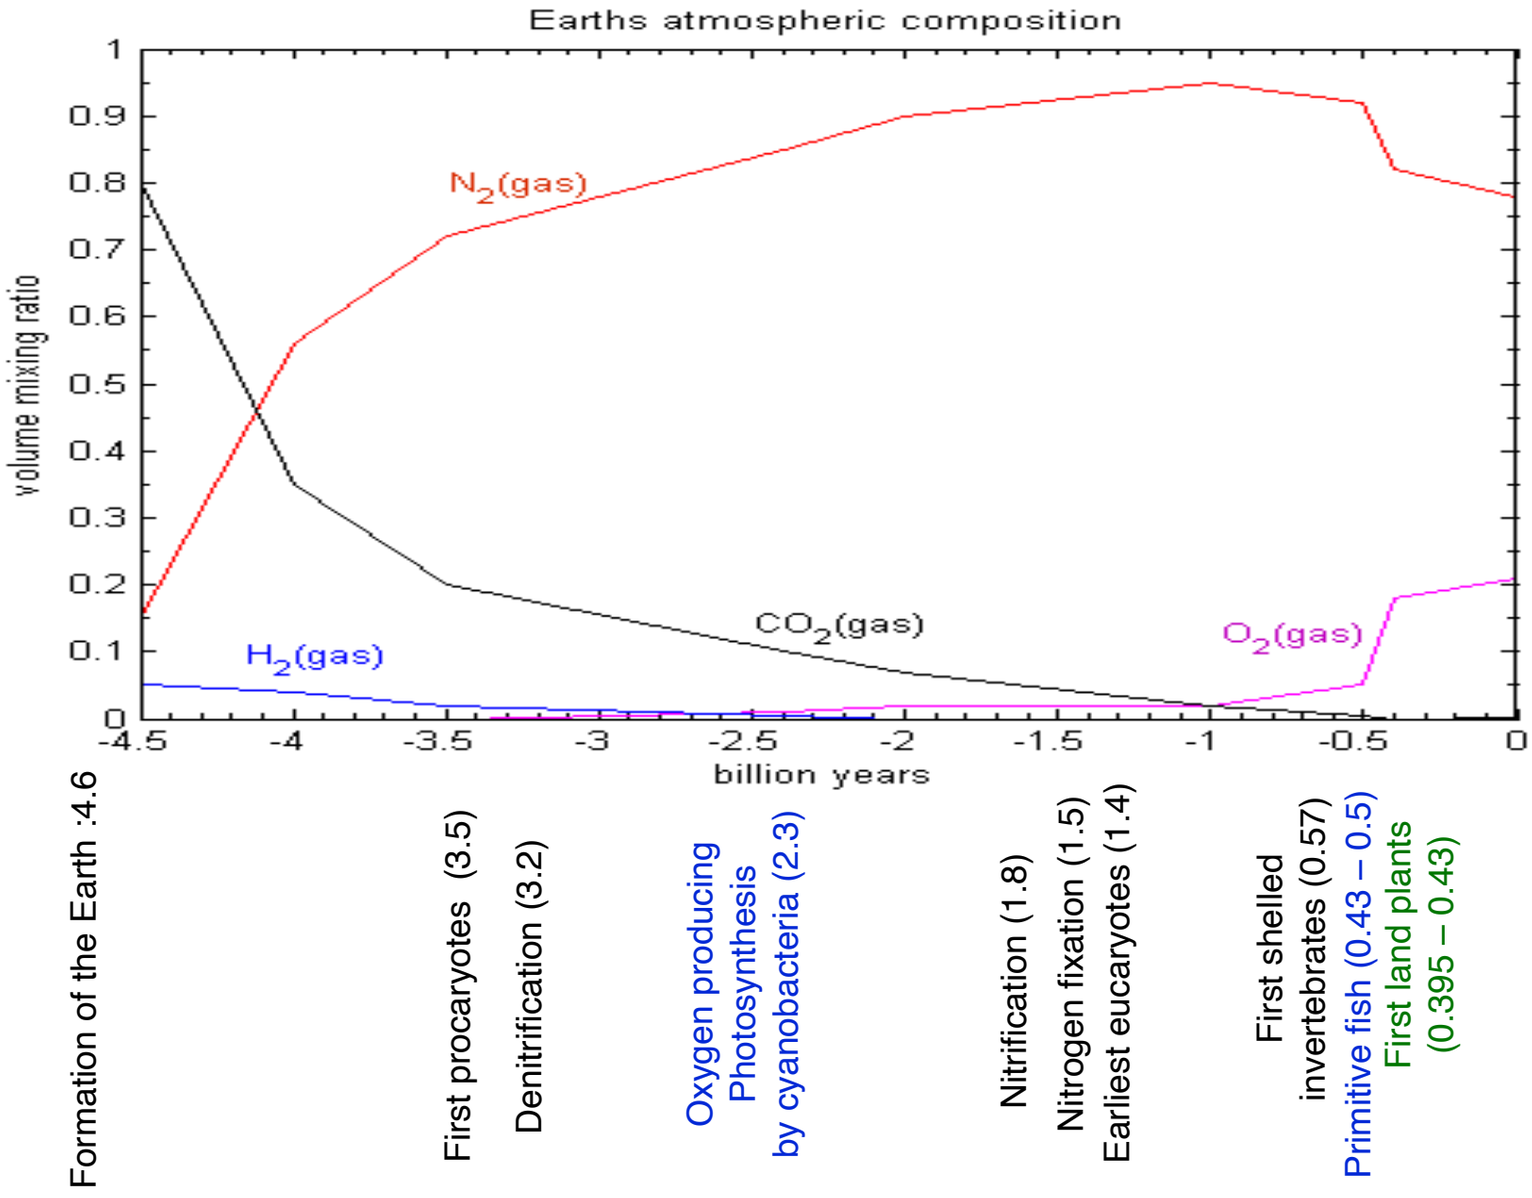
Multi box model: we can add feedback



one possible suggestion, no feedback...



History of Earths atmospheric composition



Jacobson, 2002

A note on volcanic carbon dioxide

- Volcanos and magmatically active regions on land and in the oceans emit yearly **280 - 360 million** tonnes 0.28 - 0.36 GT/yr CO2
- Humans emit yearly ~**40 billion** tonnes or 40 GT/yr CO2 (2023)
- That is **~110 - 140 times the volcanic source per year!**

- It takes **just 3 days** for humankind to emit the same as all volcanoes do **in one year**!
- There are about ~60 active Volcanoes per year!

Humans add ~7500 Volcanoes!

per year!

Bárðabunga eruption Iceland, Sept. 2014 Photo Steffen M. Noe

Task - Try to express the Estonian annual emission in Volcanoes

1: Find Estonia’s annual CO2 emission

https://globalcarbonatlas.org/emissions/carbon-emissions/

2: Relate it with the Volcano emission

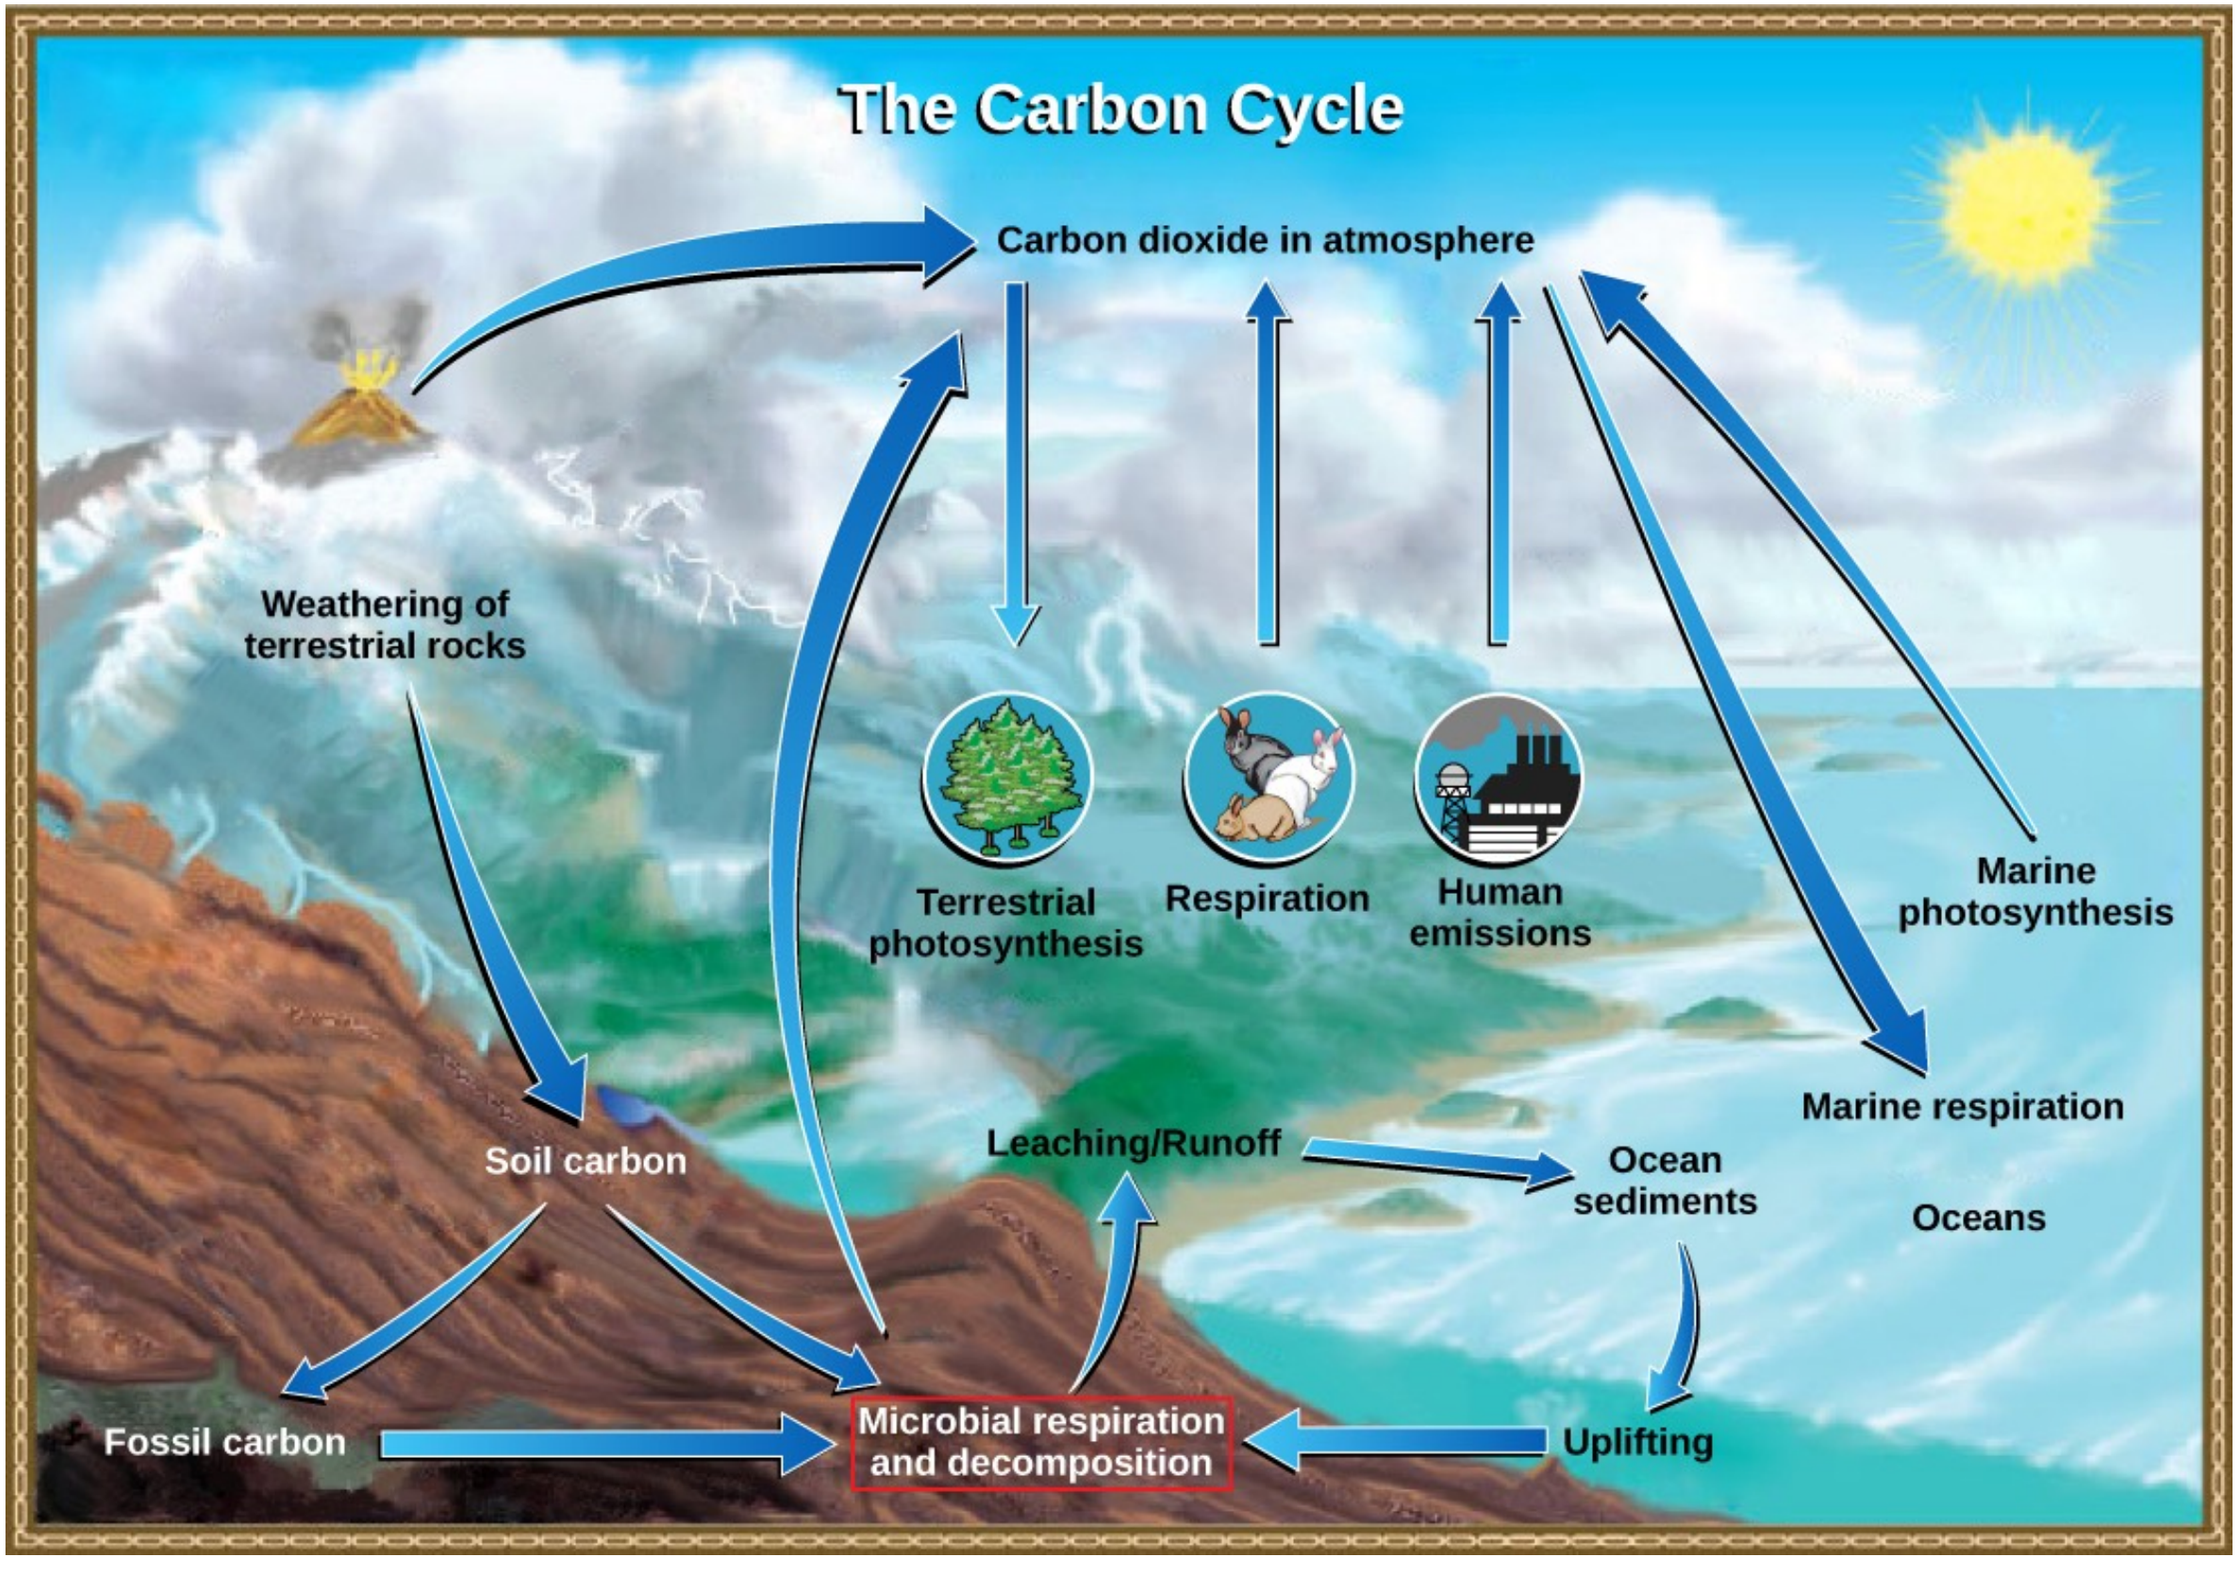
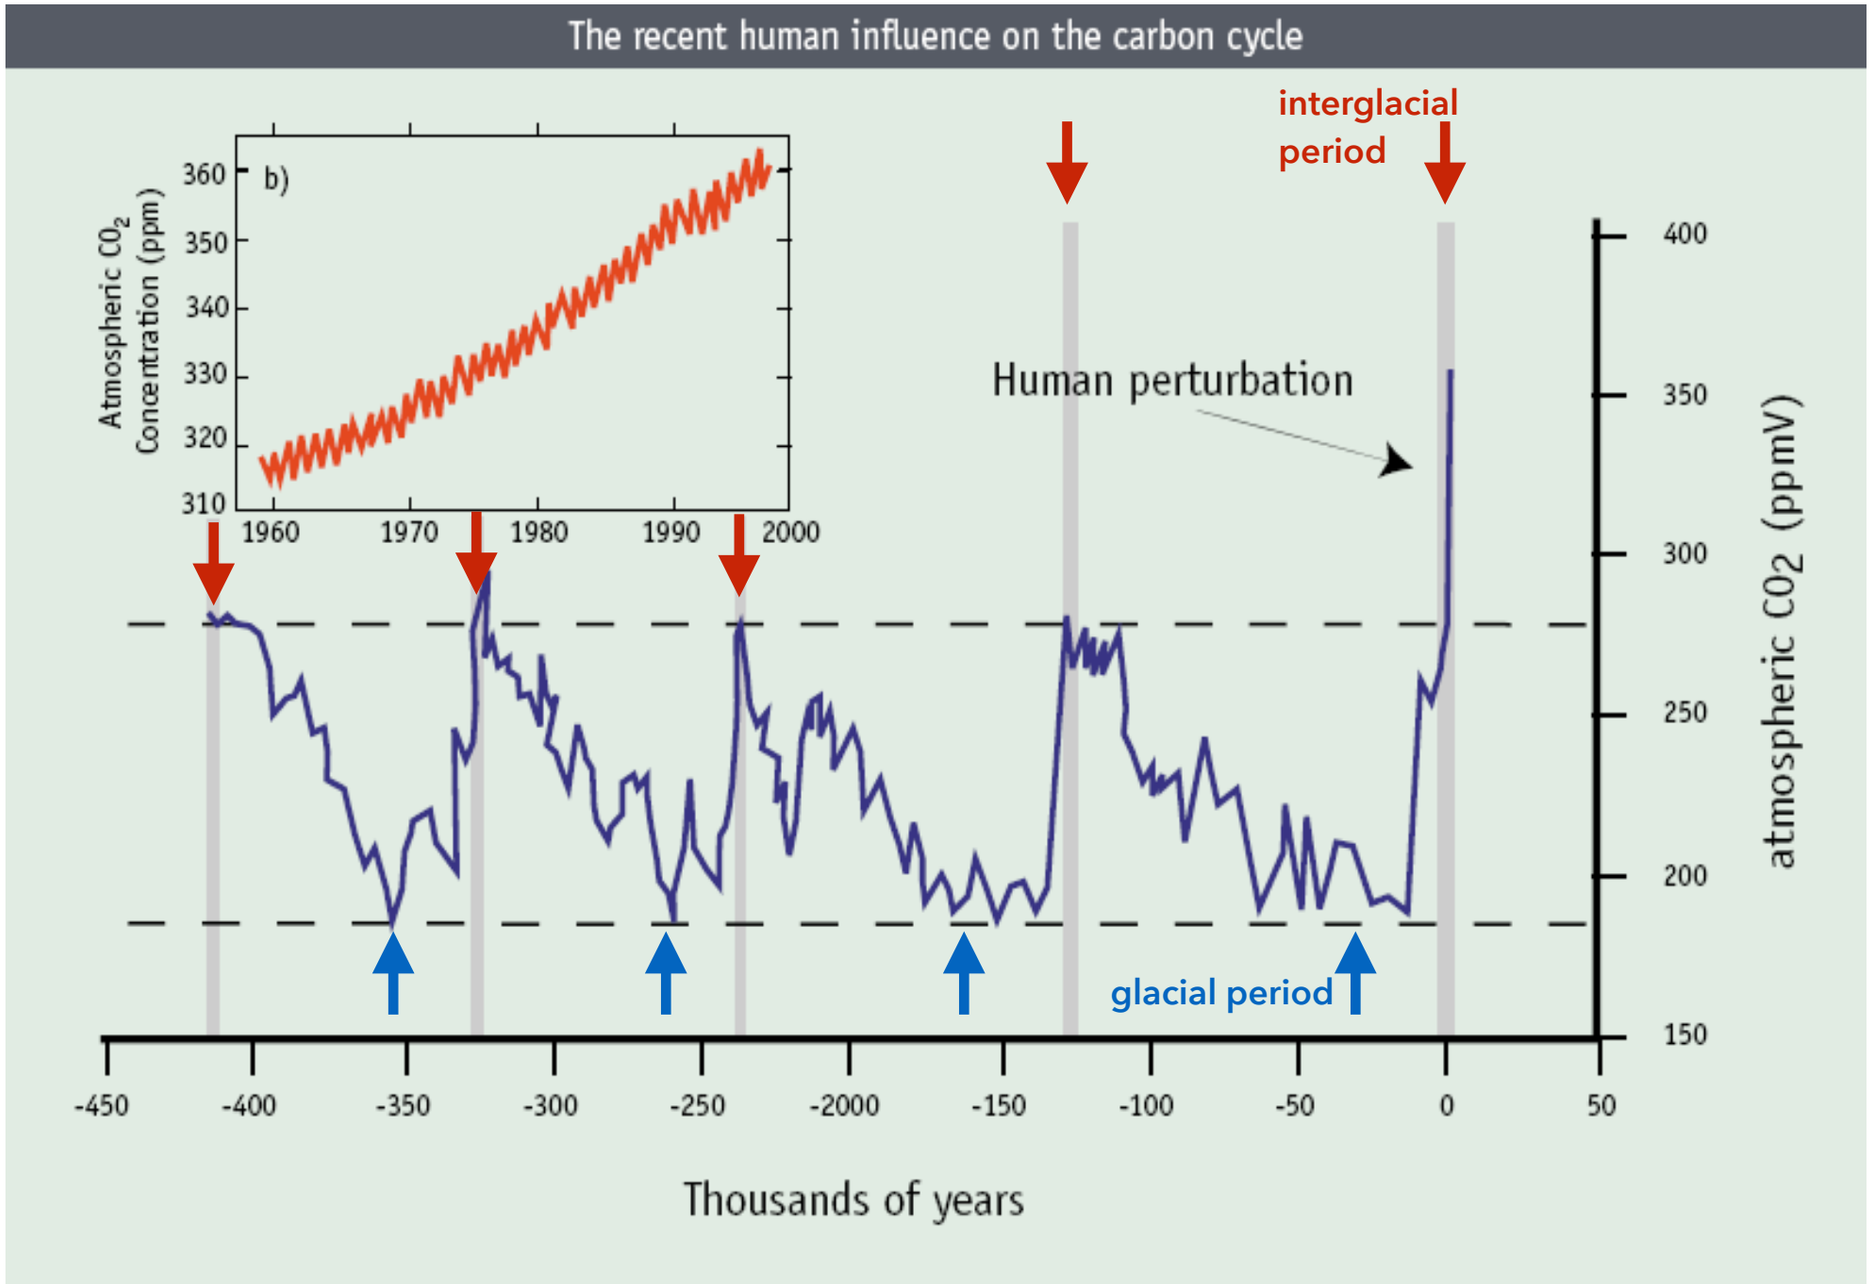
Carbon cycle



CO_2 over the past 400 000 years

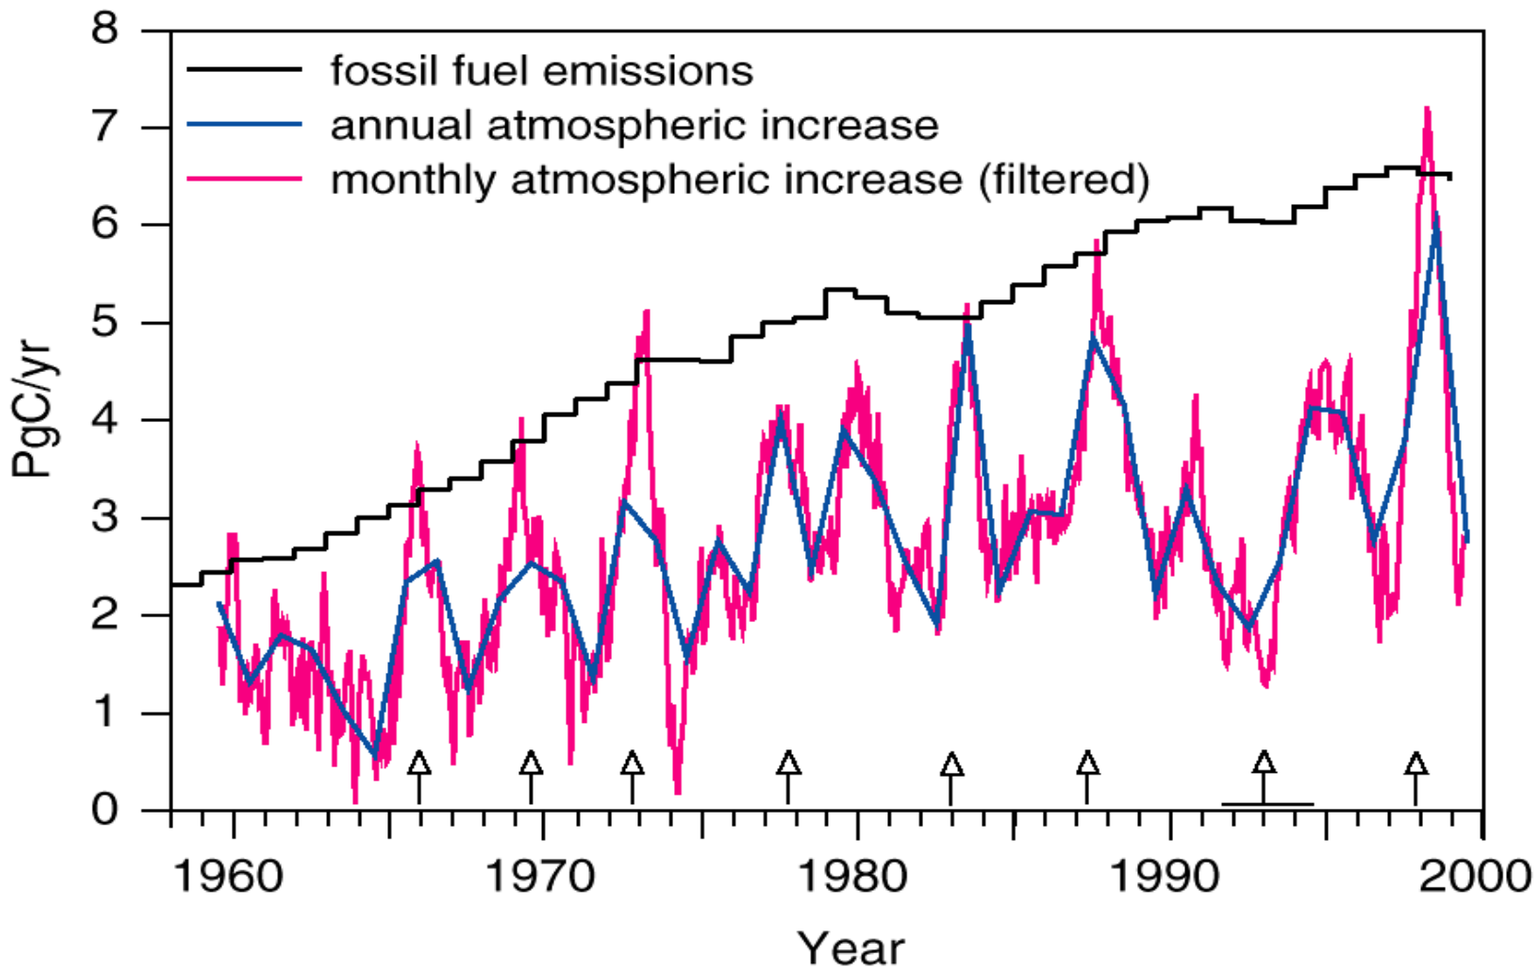


Vostok ice core data set, Petit et al., 1999

Recent atmospheric CO_2 growth rates

Notice:

- atmospheric increase is ~50% of fossil fuel emissions
- large inter-annual variability



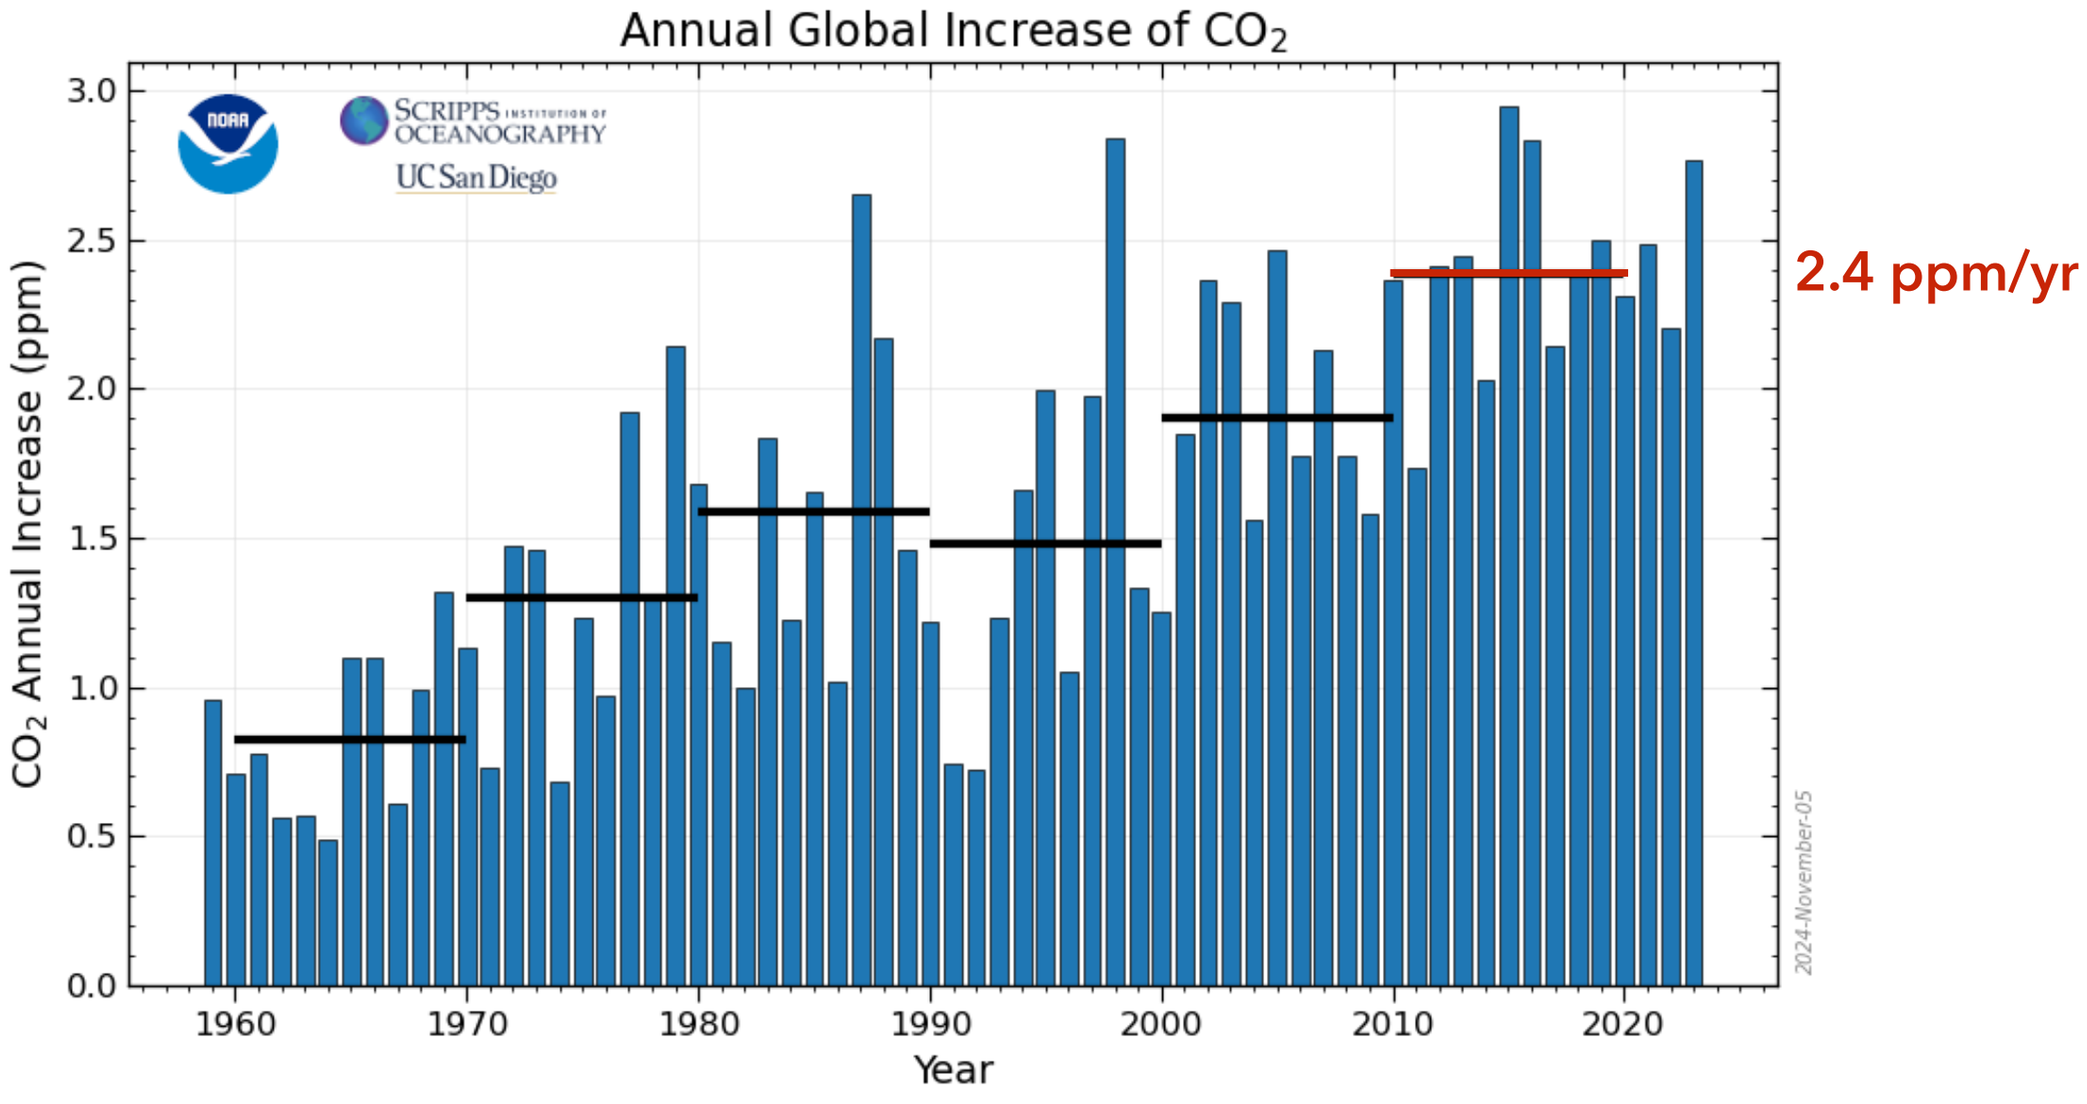
Arrows indicate
El Nino events

D.J. Jacob

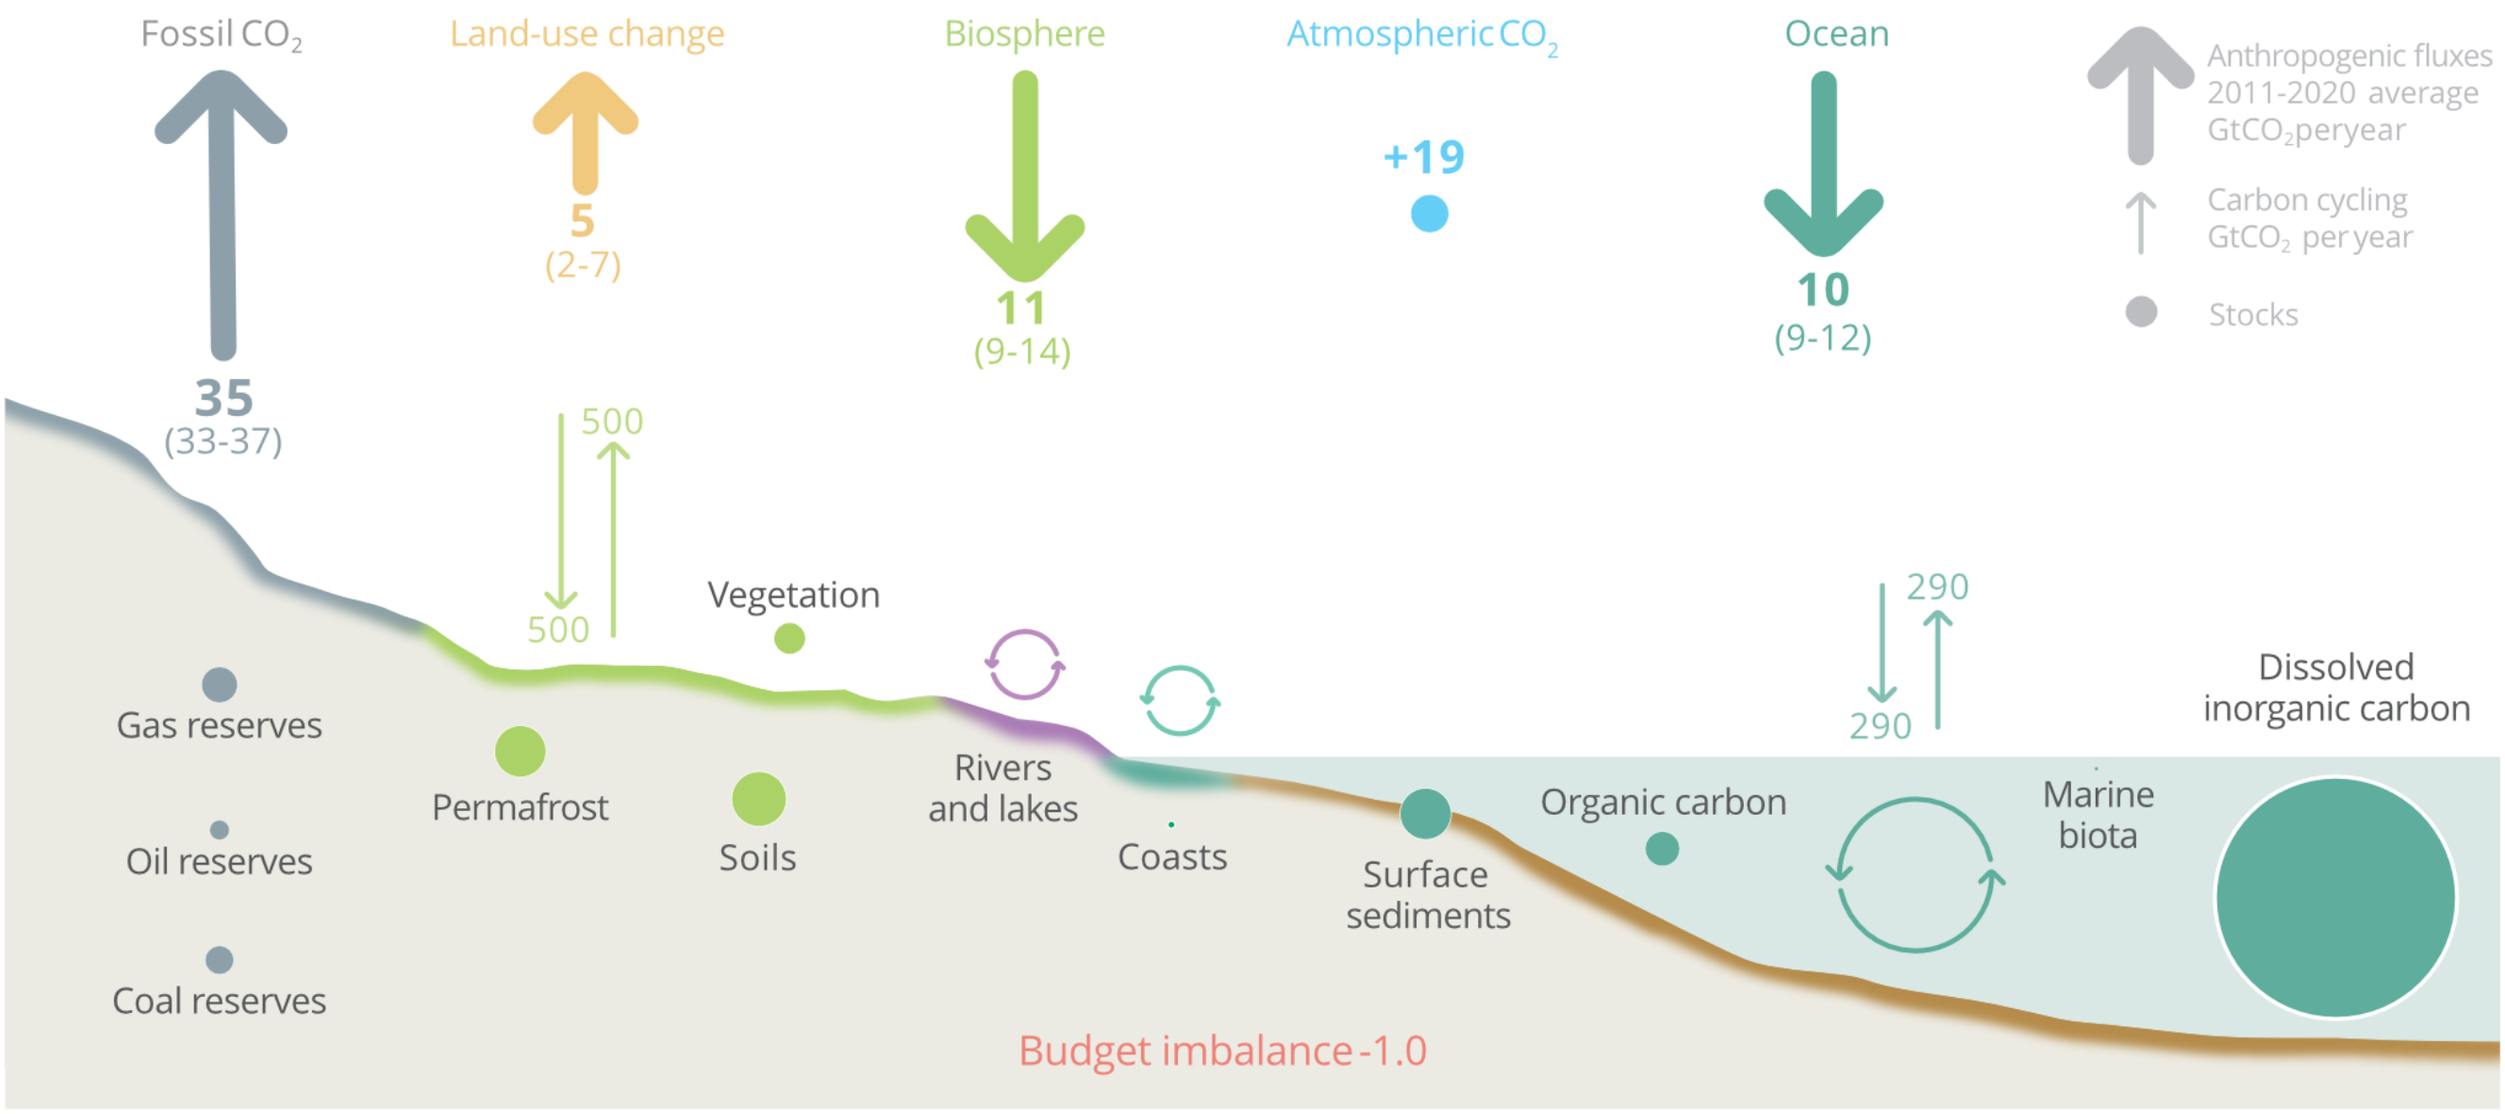
Recent atmospheric CO_2 growth rates until 2022

Notice:

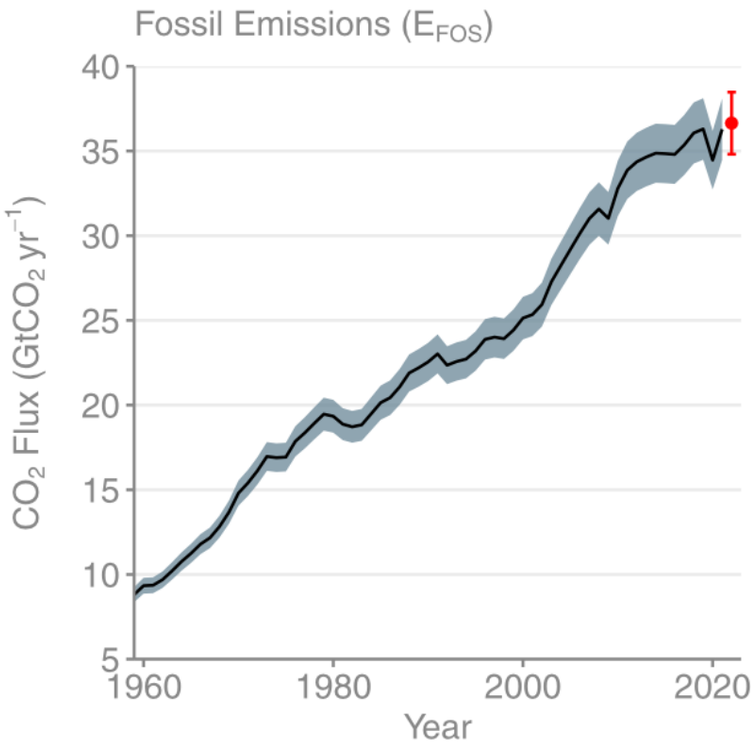
- atmospheric increase is ~50% of fossil fuel emissions
- large inter-annual variability

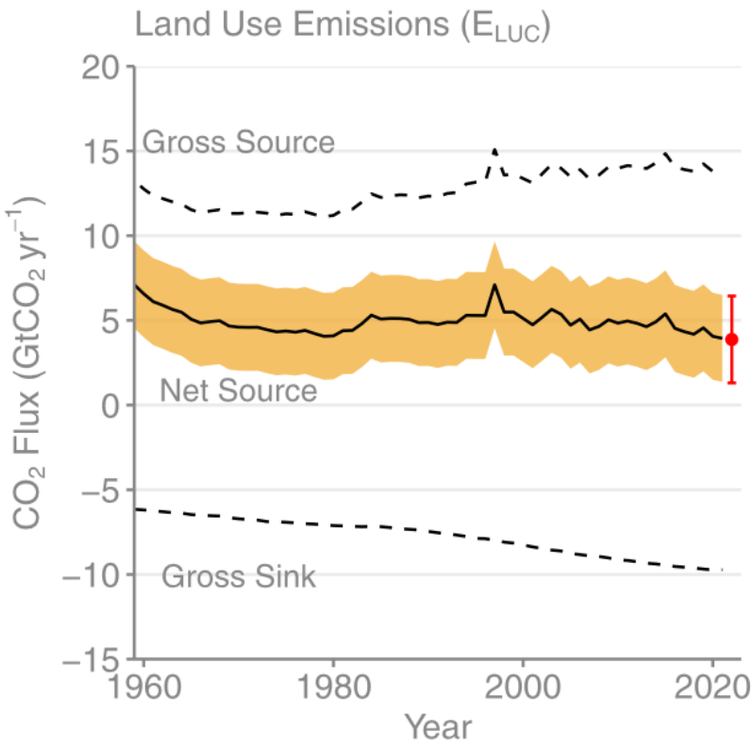


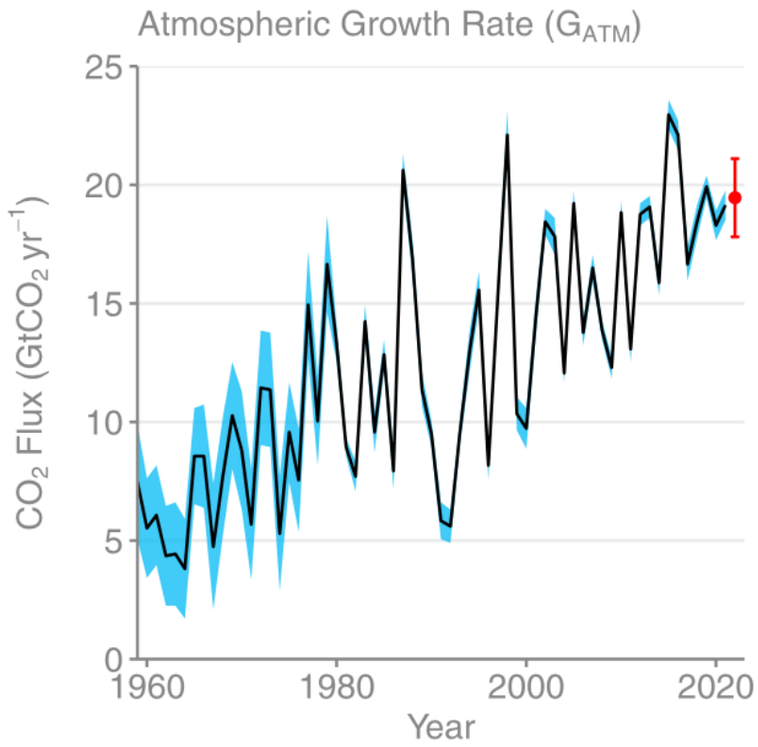
Carbon fluxes schematic (2022)

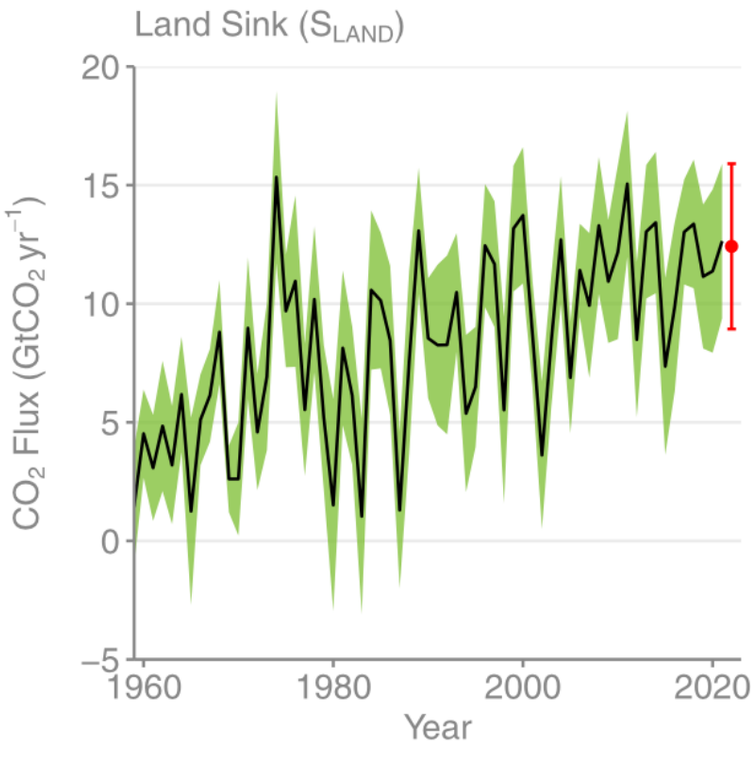


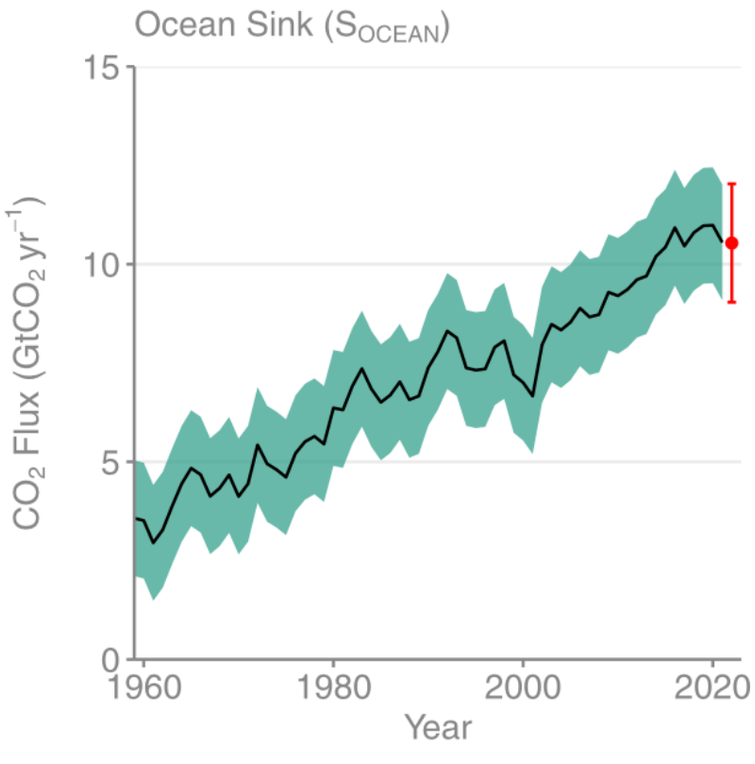
Changes in the sources/sinks over time

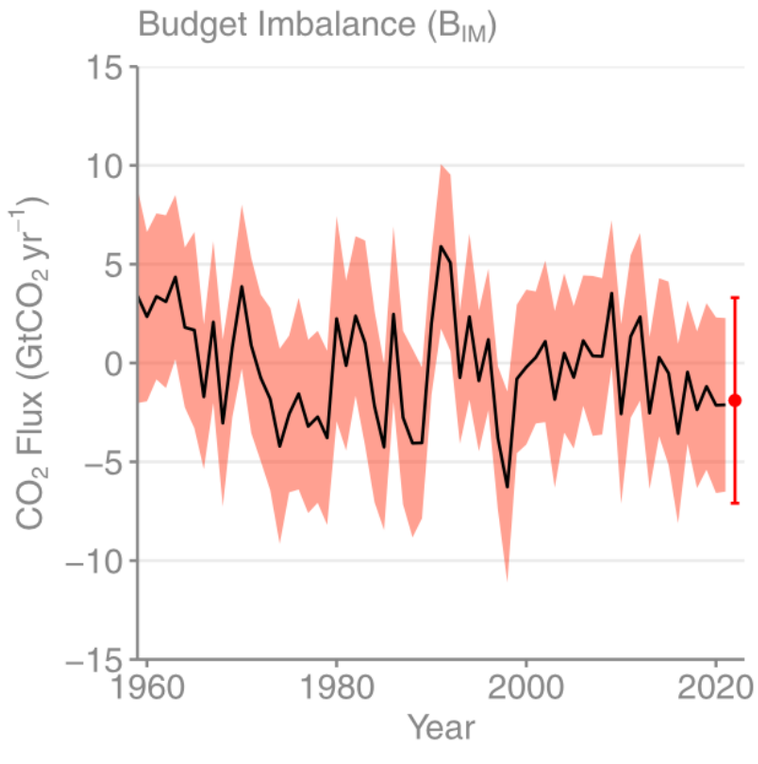












CO_2 ocean uptake chemistry

ATMOSPHERE $CO_2(g)$

OCEAN

$K_H = 3x10^{-2}$ M atm^{-1}

$CO_2 \cdot H_2O$

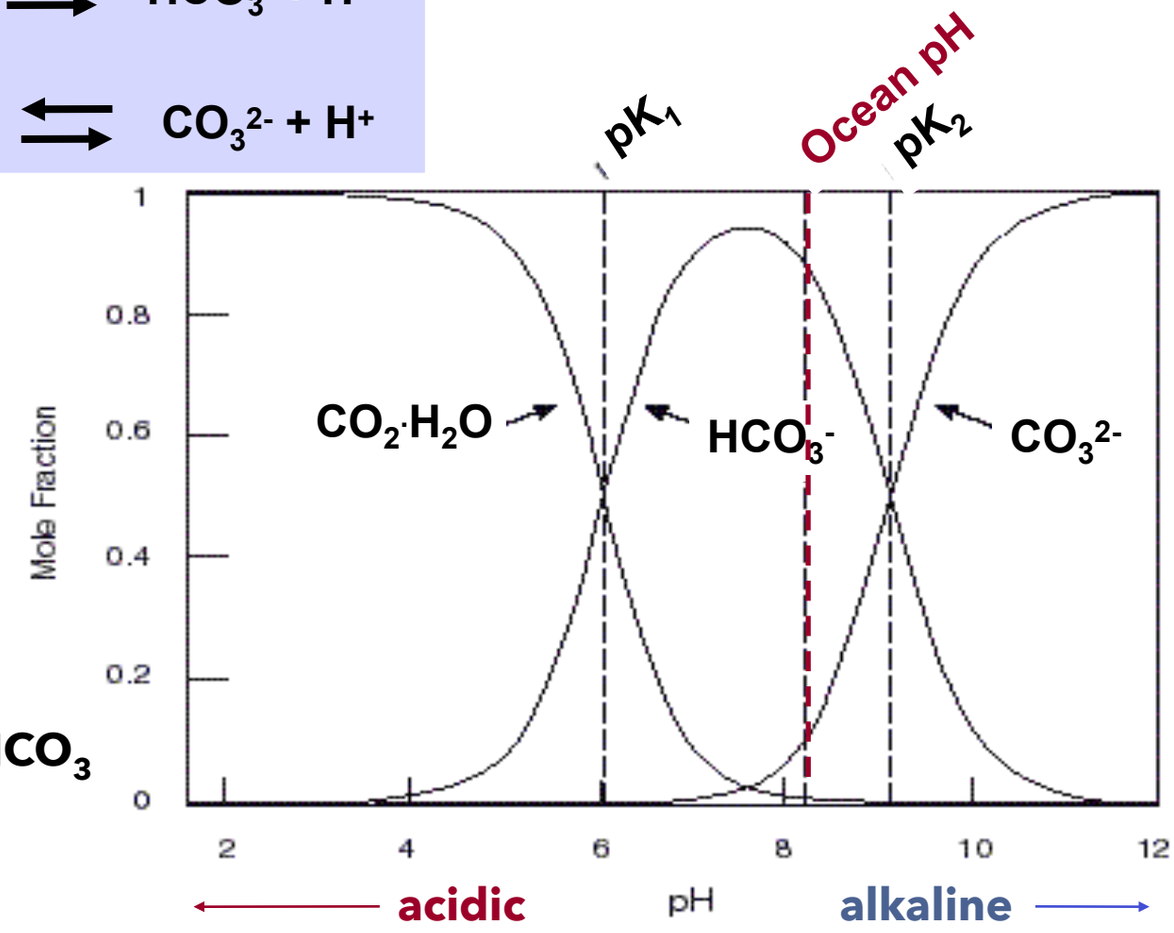
$K_1 = 9x10^{-7}$ M $\quad CO_2 \cdot H_2O \rightleftharpoons HCO_3^- + H^+$

$K_2 = 7x10^{-10}$ M $\quad HCO_3^- \rightleftharpoons CO_3^{2-} + H^+$

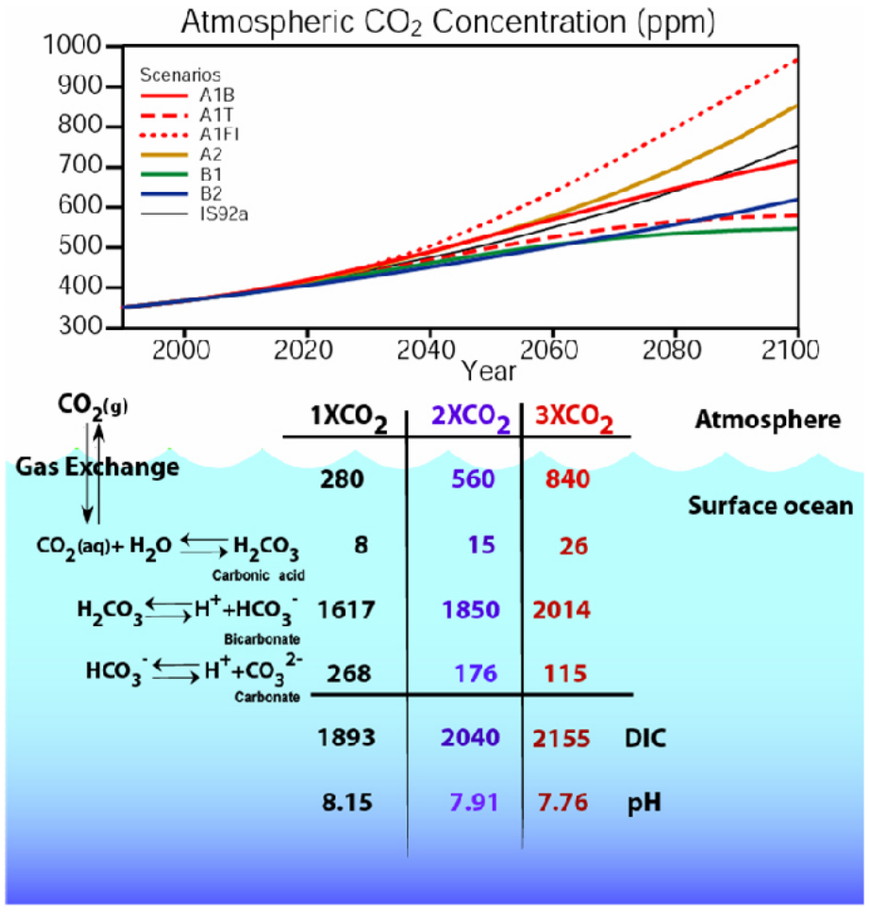
K: equilibrium constants for partitioning

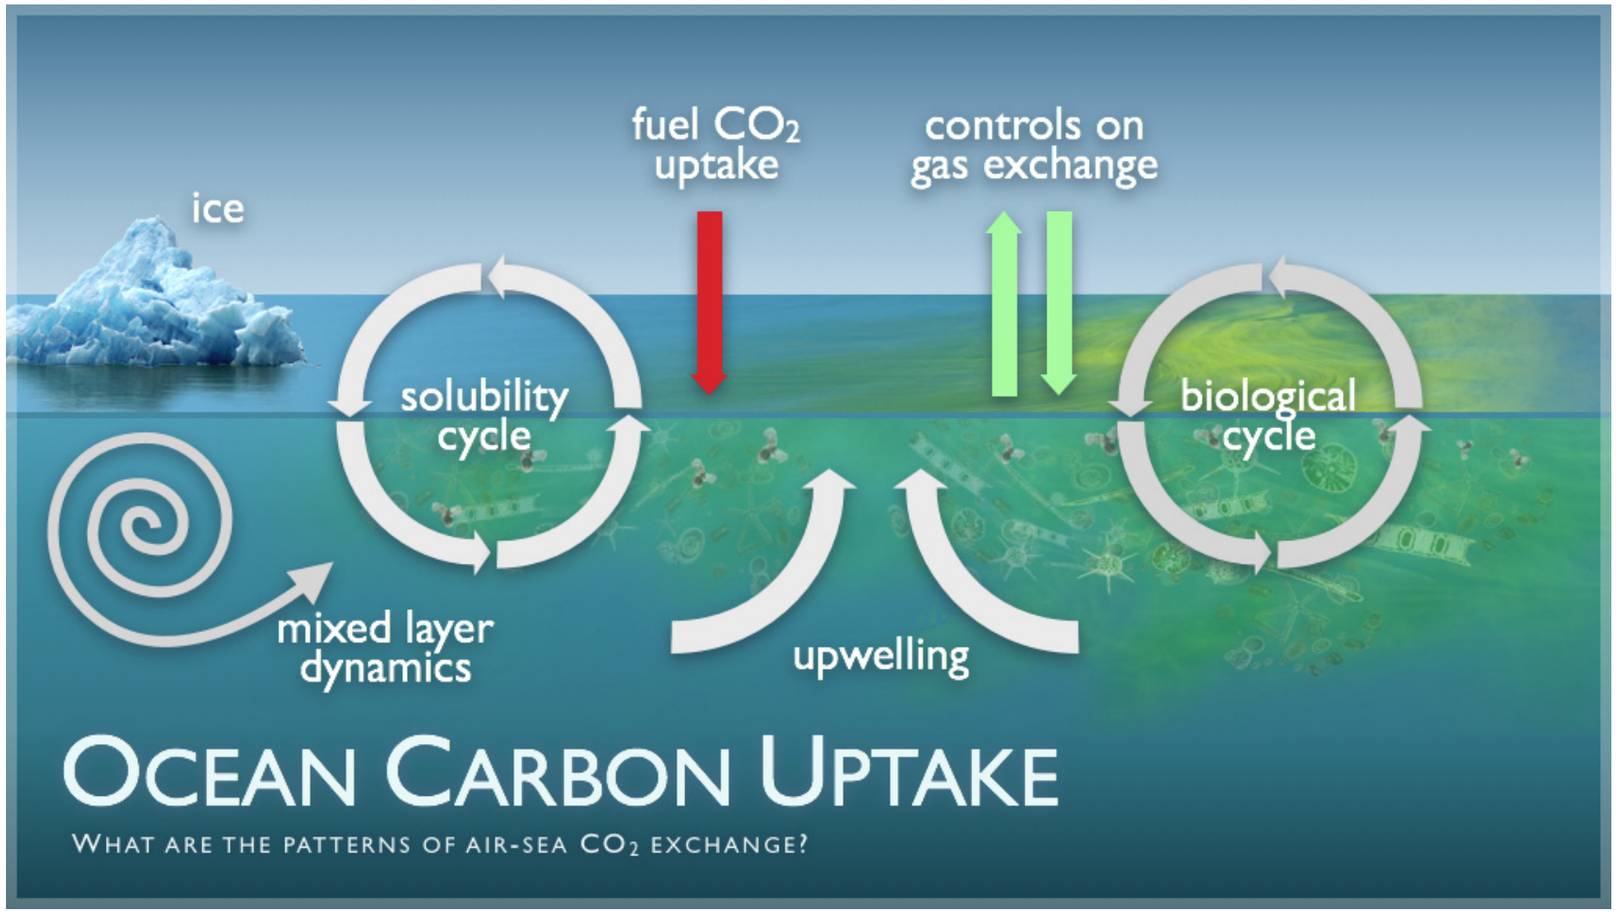
Net uptake:

$CO_2(g) + CO_3^{2-} \rightleftharpoons 2HCO_3$



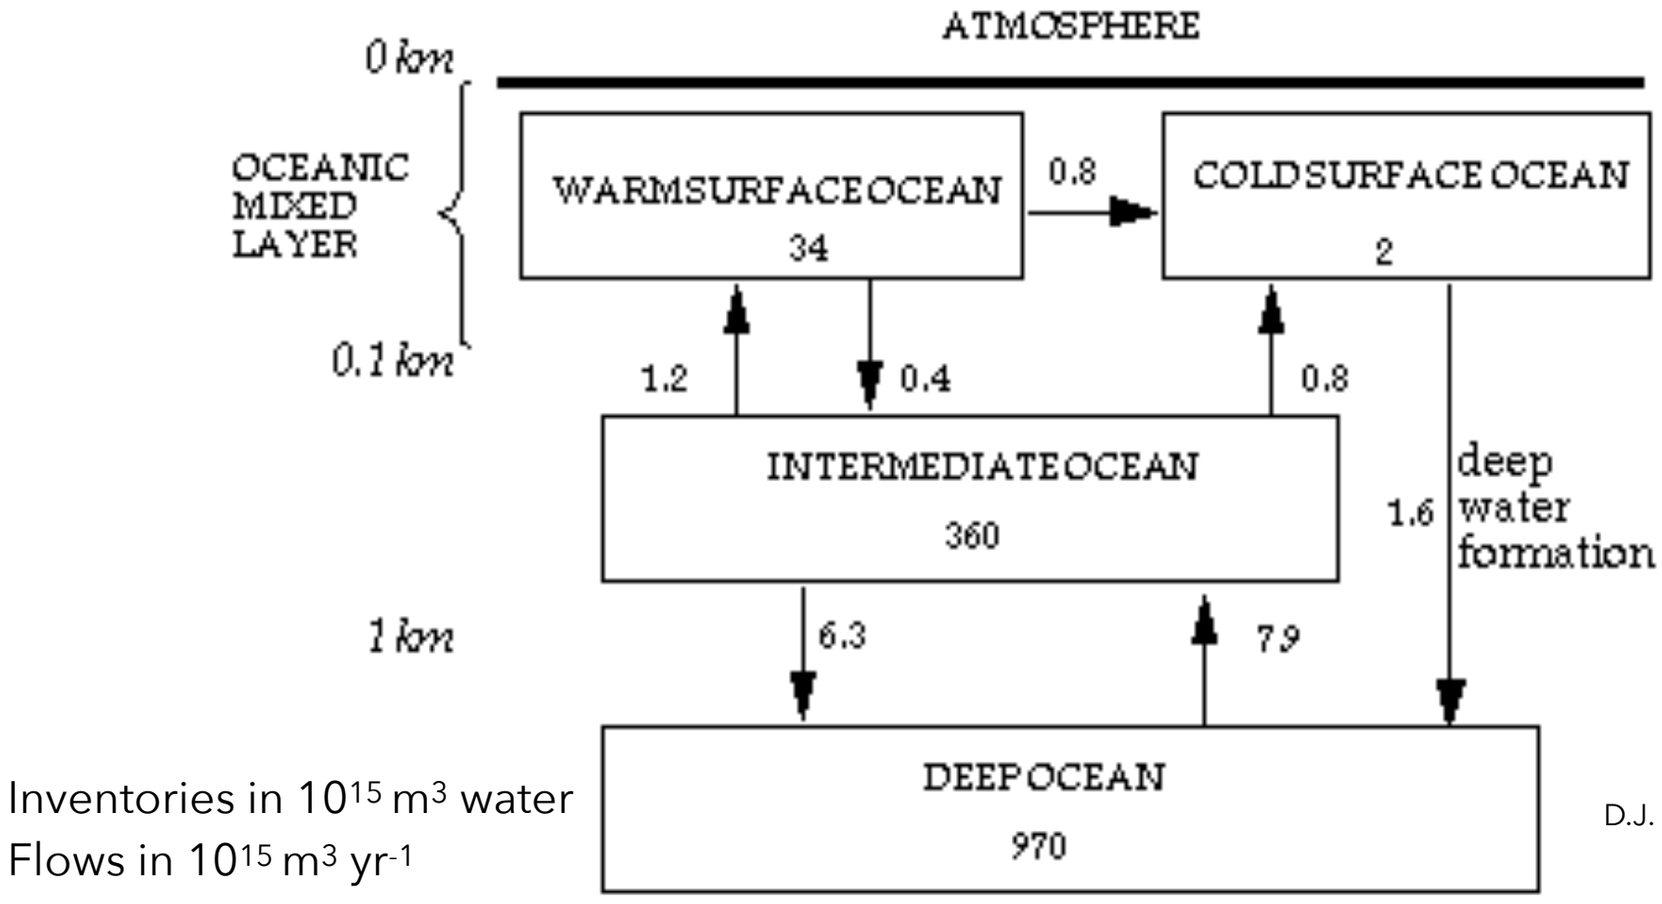
CO_2 ocean uptake - it's more than chemistry





Limits for ocean uptake

slow ocean turnover time (~200 years)



Inventories in 10^{15} m^3 water
Flows in 10^{15} m^3 yr^{-1}

D.J. Jacob

Uptake by oceanic mixed layer only (V_{OC}= 3.6×10^{16} m^3)
would give f = 0.94 (94% of added CO_2 remains in atmosphere)

Uptake by the terrestrial biosphere

(1.4 Pg C yr^{-1} in the 1990s; IPCC [2001])
is a small residual of large atmosphere-biosphere exchange

- Gross primary production (GPP):
  GPP = CO_2 uptake by photosynthesis = 120 Pg C yr^{-1}

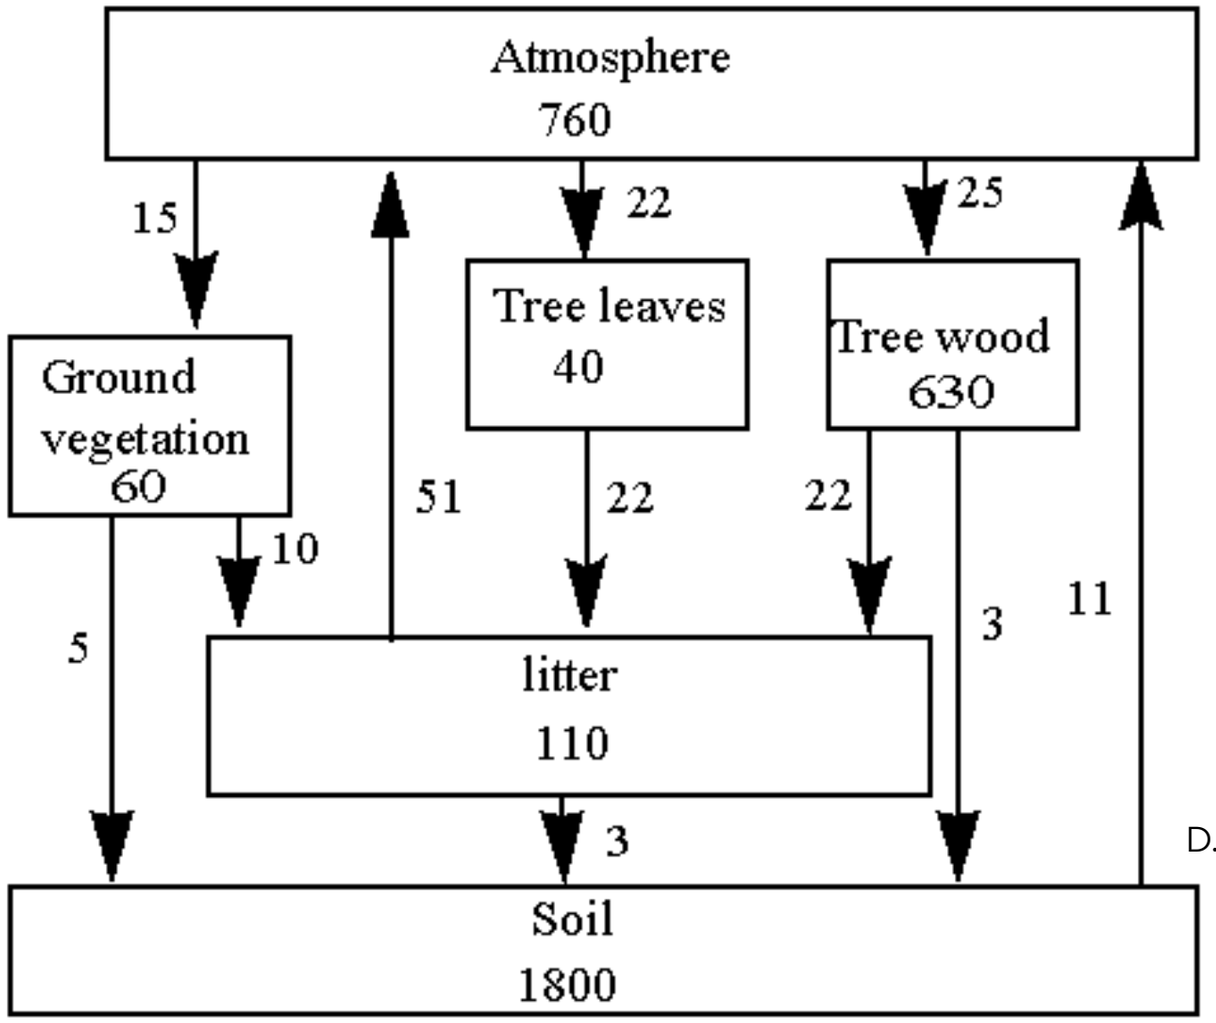
- Net primary production (NPP):
  NPP = GPP – "autotrophic" respiration by green plants = 60 Pg C yr^{-1}

- Net ecosystem production (NEP):
  NEP = NPP – "heterotrophic" respiration by decomposers = 10 Pg C yr^{-1}

- Net biome production (NBP)
  NBP = NEP – fires/erosion/harvesting = 1.4 Pg C yr^{-1}

Atmospheric CO_2 observations show that the net uptake is at northern midlatitudes but cannot resolve American vs. Eurasian contributions

Box model of carbon cycling with terrestrial biosphere

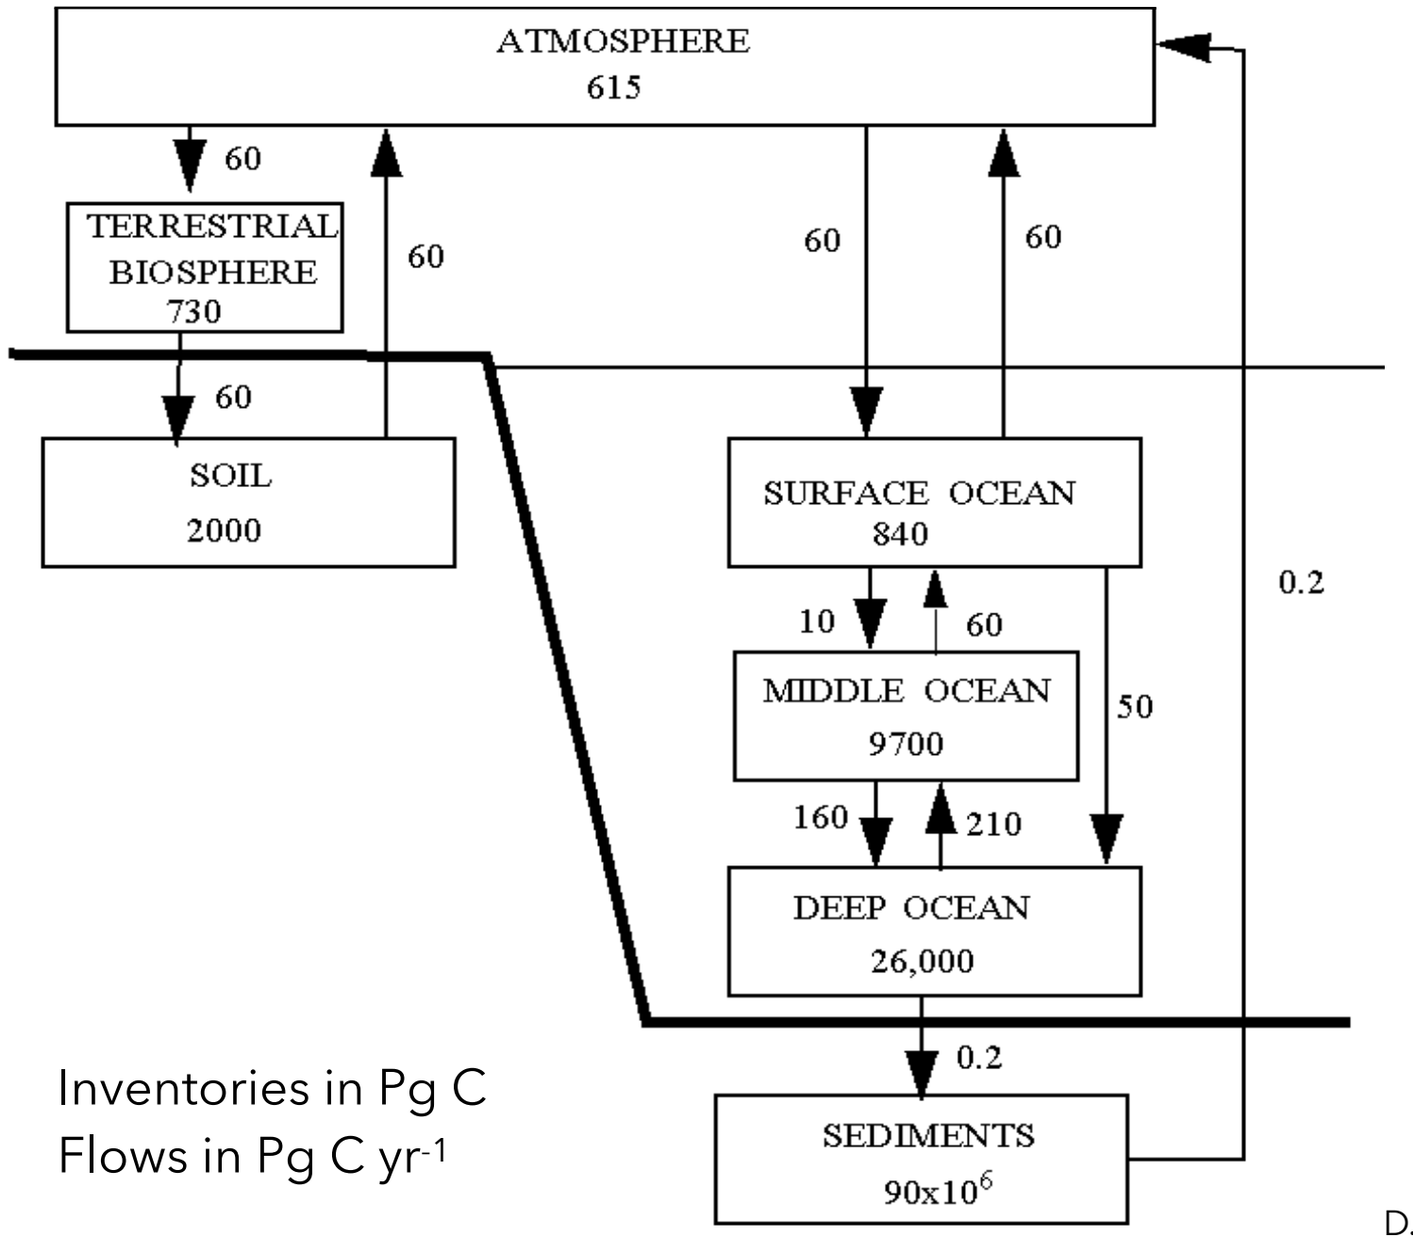


D.J. Jacob

Inventories in Pg C
Flows in Pg C yr^{-1}

Time scales are short → net uptake from reforestation is transitory

Box model of the pre-industrial global carbon cycle

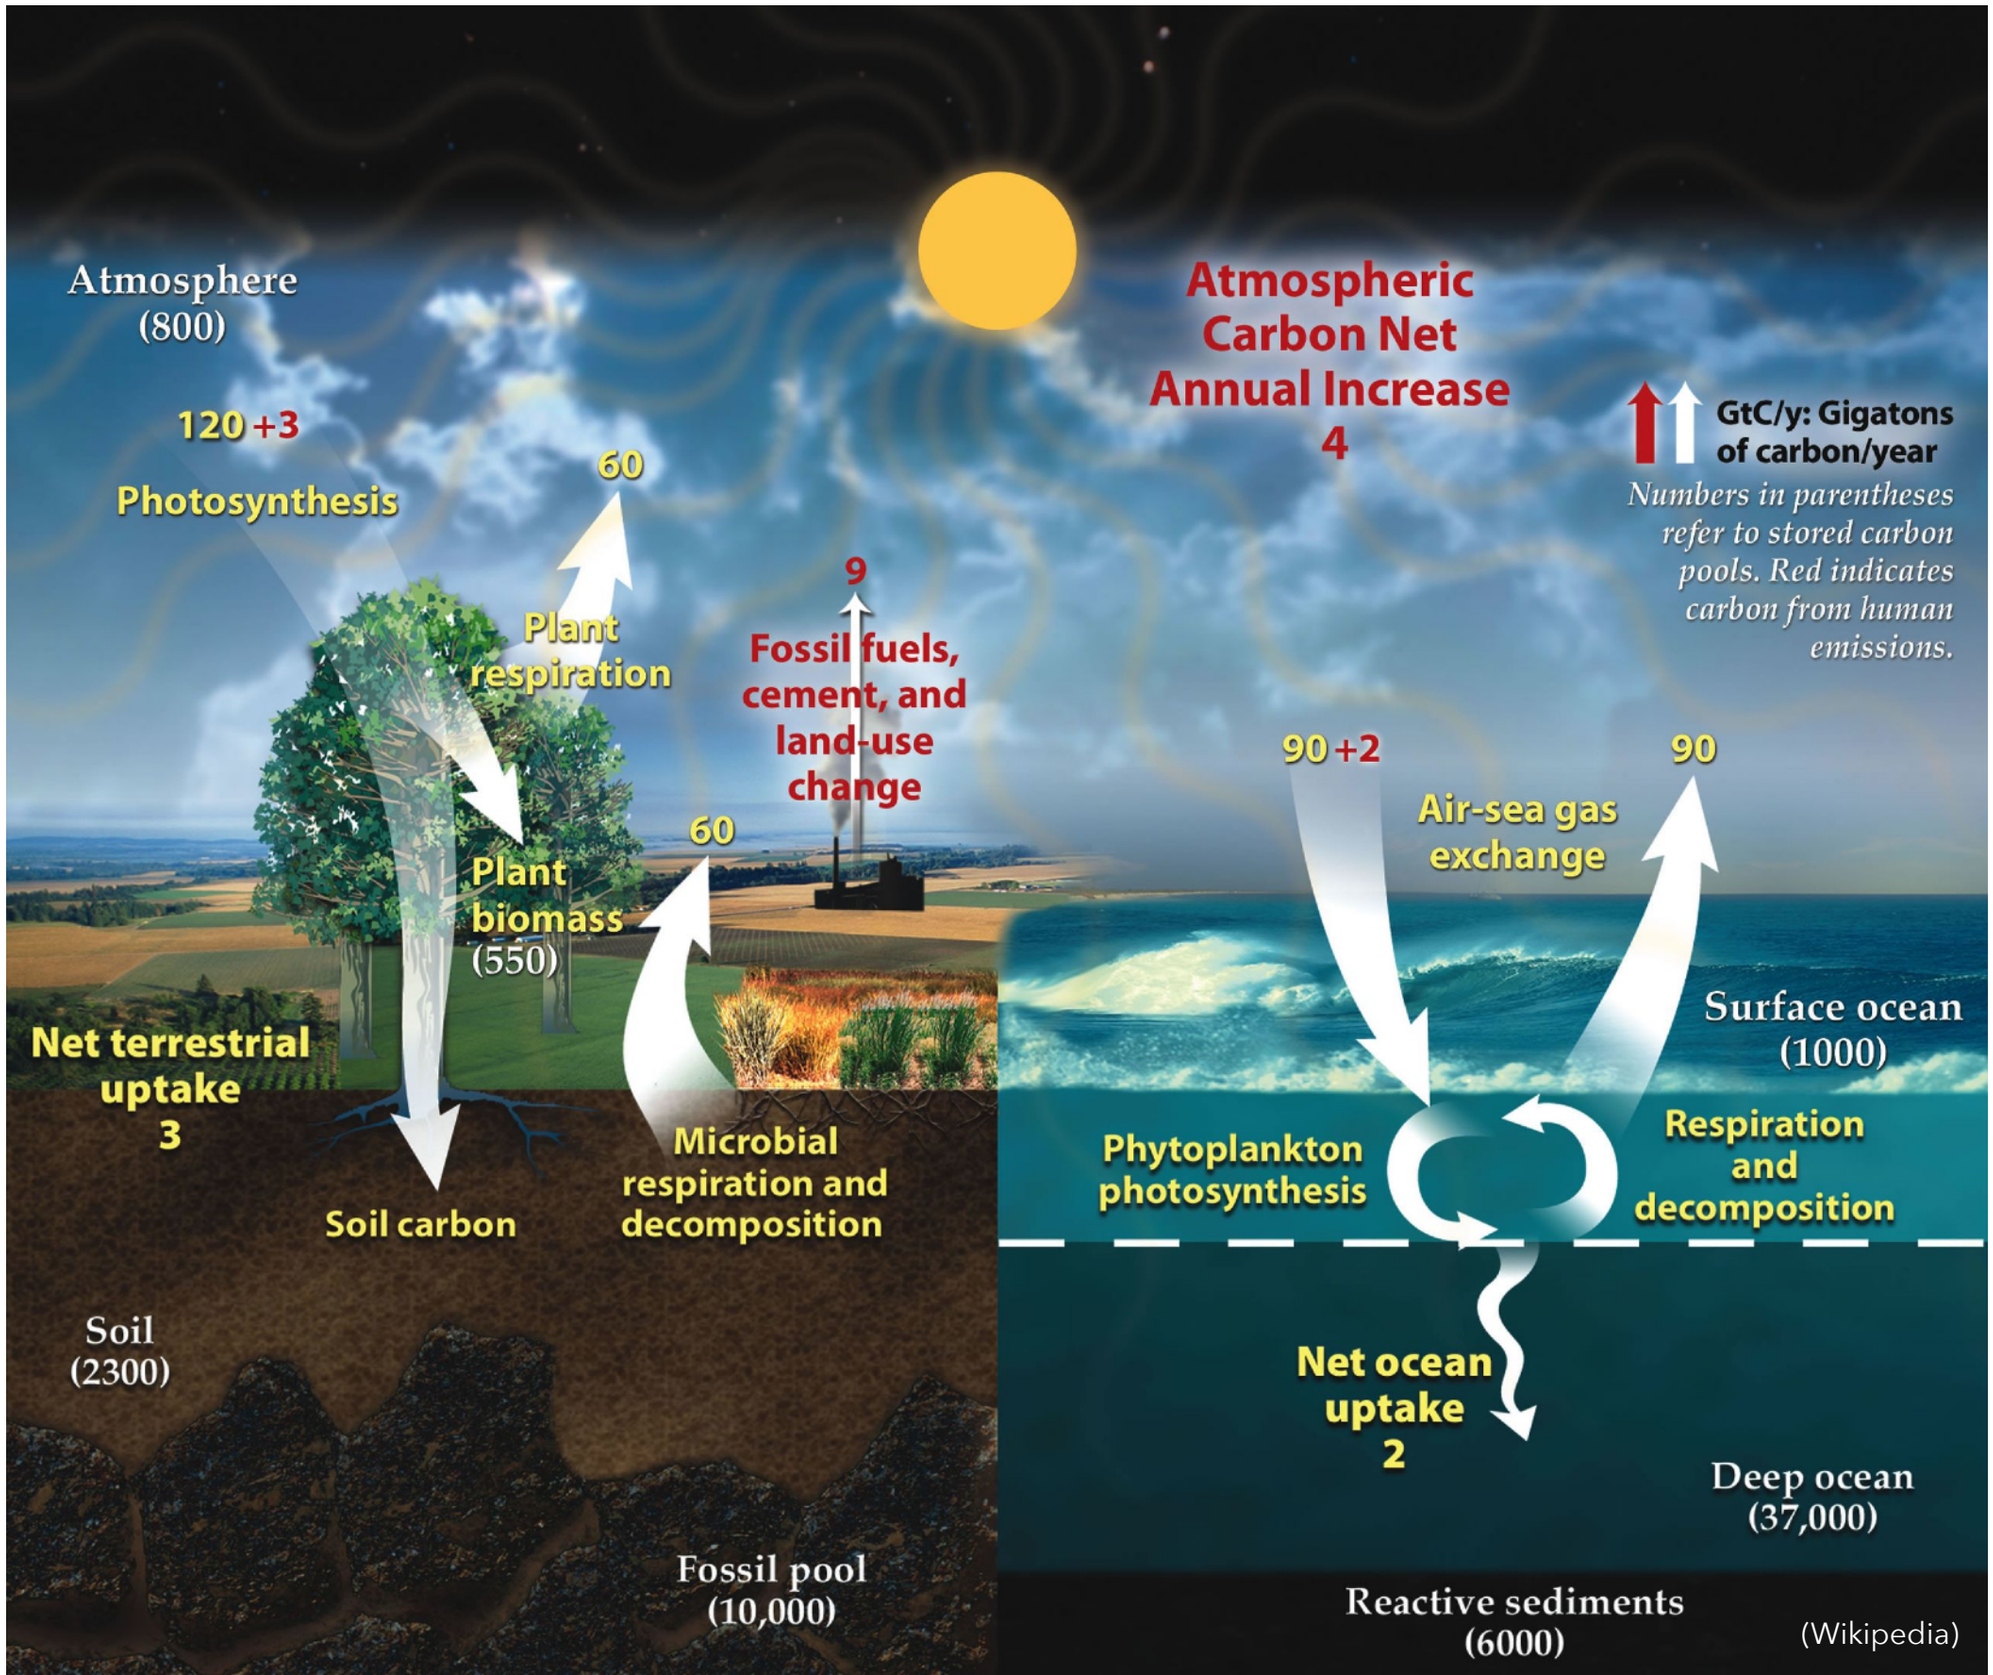


Inventories in Pg C

Flows in Pg C yr^{-1}

D.J. Jacob

Carbon cycle incl. human activity



(Wikipedia)

Tasks

Carbon/Nitrogen cycle:
-find newer numbers for the stock/inventory
-compare with older numbers in the presentation
